

Volume 71 Number 1
JANUARY 1956

Published since 1878

CONTENTS

Some problems for research in mortality and morbidity...	<i>Harold F. Dorn.</i>	Page 1
Effects of low-level radioactivity in the Columbia River...	<i>Croswell Henderson. Gordon G. Robeck, and Ralph C. Palange.</i>	6
An epidemiological approach to traffic accidents.....	<i>William G. Beadenkopf, Adele K. Polan, Walter E. Bock, Robert F. Korn, and George James.</i>	15
The state of the Nation's public health services.....		25
Opportunities for nationwide cooperation.....	<i>Marion B. Folsom.</i>	25
The wide spectrum of our health services.....	<i>Leonard A. Scheele.</i>	26
Current trends in child health.....	<i>Martha M. Eliot.</i>	33
Community air pollution, a developing health problem.	<i>Justin M. Andrews.</i>	37
Research factors in the control of uterine cancer.....	<i>Raymond F. Kaiser.</i>	41
Public health aspects of atomic energy in peacetime..	<i>Daniel Bergsma.</i>	43
The current status of hospital survey and construction programs ...	<i>John W. Cronin.</i>	47
Food and drug projects of interest to State health officers....	<i>Jack M. Curtis.</i>	49

CONTENTS *continued*

Willamette Valley chest X-ray survey..... <i>Gordon C. Edwards.</i>	Page 53
Public health awards..... <i>Homer N. Calver.</i>	62
Public health research in chronic disease..... <i>John E. Dunn, Jr.</i>	67
As more people live longer.....	75
Survival of enteric organisms in sea water—A review of the literature..... <i>Arnold E. Greenberg.</i>	77
Measuring reactions to air pollution..... <i>John J. Phair and Maurice L. Thomson.</i>	87
Environmental causes of lung cancer..... <i>W. C. Hueper.</i>	94
Epidemic outbreak of poliomyelitis in Puerto Rico—Pre- liminary report..... <i>Juan A. Pons.</i>	99
Short reports and announcements:	
Poliomyelitis vaccine injections.....	5
Chlortetracycline as a preservative.....	66
Technical publications.....	74
Federal surplus property.....	76
CDC course in epidemiology for nurses.....	86

Published concurrently with this issue:

PUBLIC HEALTH MONOGRAPH No. 36 . . . A quest
into the environmental causes of cancer of the lung.
W. C. Hueper.

54 pages; illustrated. An interpretive article and information on
availability appear on pages 94-98.

Relationships of health to demographic characteristics warrant further examination and study in the United States.

Some Problems for Research in Mortality and Morbidity

By HAROLD F. DORN, Ph.D.

THE COLLECTION, compilation, and publication of vital statistics are among the major activities of every public health agency. Too frequently the collection and preparation for publication of vital statistics require such a large proportion of the time and energy of available personnel that the analysis and interpretation of these data are neglected. Yet without analysis and interpretation, vital statistics remain relatively sterile.

Nearly a century ago the great English vital statistician, William Farr, began his analysis of official mortality records in order to discover and point out significant variations in ill health among various groups of the population. The work he initiated has been continued and expanded by succeeding registrars general. The most extensive information concerning variations in mortality rates by occupation and socioeconomic classes available anywhere is that for England and Wales.

The United States does not have a series of analyses of mortality statistics comparable to those of England and Wales. The first third of

this century was devoted to establishing a complete registration system covering the entire United States. Mortality and natality statistics for the entire country first became available in 1933.

A test of birth registration completeness made at the time of the 1950 census of population revealed that a birth certificate was on file for 98.6 percent of white infants and for 93.5 percent of nonwhite infants born during the first quarter of 1950.

Although a comprehensive study of the completeness of death registration has never been made, the relative amount of under-registration probably is negligible except for some rural areas whose aggregate population is not large. The relative amount of under-registration of infant deaths may be somewhat greater than that for deaths of persons aged 1 year or older. In computing the 1939-41 life tables, the National Office of Vital Statistics assumed that the relative under-registration of infant deaths was approximately equal to that of births. However, this assumption has never been tested by an actual field study.

Dr. Dorn is chief of the Office of Biometry, National Institutes of Health, Public Health Service, Bethesda, Md. This article is based on a paper delivered at the annual meeting of the Population Association of America at Princeton, N. J., May 1955.

Rural and Urban Differences in Mortality

One of the first illustrations of mortality differences in medical literature was the higher death rate among city dwellers in contrast to rural residents. Although this difference gen-

erally is assumed to exist at the present time, no comprehensive study of the problem has been made in recent years.

Mortality statistics classified by the place of residence of the deceased were first published by age, sex, race, and size of community for deaths occurring in 1940. These were available for each State for all causes combined and for a limited number of important causes for both sexes combined for the entire United States. A supplementary volume (1) presented data for the 2-year period, 1939-40, for each city of 100,000 or more population, by leading causes of death, age, and race and for each county and city of 10,000 or more population for all causes. By the time these data were published in 1943, World War II was in progress so that a systematic analysis of the 1940 mortality tabulations was not conducted.

Two important changes affecting the use of mortality statistics were introduced in the 1950 census of population: the change in the definition of the urban population to include the urban fringe of cities of 50,000 or more population and the delineation of standard metropolitan areas and standard economic areas and regions. Prior to and including 1930, urban was defined as places of 10,000 or more inhabitants in the tabulation of vital statistics, a definition that did not correspond to that used in the census of population from 1910 to 1940. In 1940, for the first time, a comparable definition of urban and rural population was used for both the enumeration of population and the tabulation of vital statistics. No practicable way of classifying vital statistics in accordance with the revised definition of urban population used in the 1950 census has yet been devised, so once again it appears that the definition of the urban population may not be the same for the two sets of statistics.

Fortunately, a reasonably satisfactory substitute for the rural-urban classification is available. Since 1950, the National Office of Vital Statistics has tabulated mortality statistics for the metropolitan and nonmetropolitan counties of each State. In general, metropolitan counties are the counties included in the standard metropolitan areas used by the Bureau of the Census. No extensive analysis of these statistics has yet been published.

Geographic Variations in Mortality

Almost a century ago, William Farr proposed that the healthiest districts of England and Wales be used as a yardstick of public health. From time to time since then, the registrar general has used this concept in the presentation and analysis of mortality data. In contrast, very little has been published in the United States concerning geographic variations in mortality rates. The range between the States with the highest and lowest mortality rates probably has been decreasing. Nevertheless, in 1950, after adjusting for differences in the age composition of the population, the highest rate still was 40 percent above the lowest rate.

State death rates by age vary much more than the average rate for all ages. For the white population in 1950, the highest rates for each age group under 55 years were approximately twice as large as the lowest rates. Above this age the range in death rates is smaller but still averages about 50 percent.

The range between the highest and lowest death rates almost certainly would be greater for areas smaller than States. The county is the preferable unit for forming such areas since the basic demographic data are available for counties and since the allocation of deaths to county of residence undoubtedly is more reliable than the allocation to rural or urban areas.

Two groupings of counties suggest themselves: metropolitan and nonmetropolitan counties within each State and the State economic areas or subregions defined by the Bureau of the Census in cooperation with other agencies. The economic subregions, although they cross State boundaries, are probably the most useful grouping of counties for the study of geographic differences in mortality rates. As no tabulation of mortality data by economic subregions has been made, a complete retabulation for one or more years around 1950 would be required.

Mortality by Occupation

The 14th Annual Report of the Registrar General of England and Wales for 1851 contained a tabulation of the deaths of males, aged 20 years or more, classified by the occupation of

the deceased. This was the first of a series of decennial reports that has been continued for 100 years. Shortly after the death registration area was established in the United States, plans were made for a study of occupational mortality around the date of the 1910 census. The 1909 volume of mortality statistics contains tables giving the number of deaths of males classified by age, occupation and cause of death. No data were published for subsequent years and so far as I can determine no analysis was ever made. A special tabulation of the census population by occupation would have been required since the death registration States of 1910 included only 51 percent of the total population of the United States.

The many discussions of the relationship of mortality rates to occupational and socioeconomic groups that have taken place in the United States since 1910 have produced few statistics. The National Tuberculosis Association published a brief analysis of mortality rates for 7 broad social and occupational classes, based upon the deaths of male workers in 10 States during 1930. Except for this study, no analysis of mortality differences among occupational or socioeconomic groups based upon official death statistics has been made in the United States.

One of the major deterrents to a study of occupational mortality has been uncertainty concerning the degree of comparability of the entries of occupation and industry on death certificates with those on the census of population schedules. A corresponding uncertainty also has prevented the analysis of official birth statistics by occupational or socioeconomic groups.

Fortunately, studies are now under way to resolve this difficulty. The Scripps Foundation in cooperation with the Bureau of the Census is planning to compare the entries for occupation and industry on a sample of birth and death certificates with corresponding information from the 1950 census schedules. In the meantime, the National Office of Vital Statistics is preparing an analysis of mortality differentials by occupation and socioeconomic class based on deaths of males from 20 to 65 years of age during 1950. The successful completion of these two projects will provide a basis for planning future studies of the relationship of mor-

talidity and fertility to occupational and socioeconomic classes in the United States.

Fetal Mortality

The rapid decline in the infant mortality rate has led some to assume that mortality during the first few months of life is now under control and that it is only a question of time until the death rate at the start of life will be lowered to the irreducible minimum. This is far from being the case. The high infant mortality rates of the past have distracted attention from the even higher fetal mortality rate. In addition, the reporting of fetal deaths has been so incomplete that a reliable estimate of fetal mortality could not be made.

In the United States, New York City probably has the longest record of registration of all fetal deaths regardless of the duration of pregnancy. In 1900 the reported infant mortality rate for New York City was 135 per 1,000 live births, and the reported fetal death rate was 45 per 1,000 live births plus fetal deaths. In 1953 the corresponding rates were 24 and 107 respectively. The increase in the fetal death rate from 45 to 107 per 1,000 probably is largely the result of improved reporting and the revision of regulations to specify more clearly that all fetal deaths, irrespective of the period of gestation, should be reported.

Registration still is seriously incomplete; during the 5 years from 1949 to 1953 the fetal death rate in New York City increased from 84 to 107 or about 27 percent. Studies of selected groups of pregnant women indicate that perhaps as many as one-half of the total fetal deaths are not reported. If generally true, this conclusion leads to an estimate that approximately 20 percent of pregnancies in New York City terminate in a fetal death and 80 percent in a live birth. Of the live births, between 2 and 3 percent die during the first year of life. In total, probably from 20 to 25 percent of pregnancies terminate either in a fetal death or in a live birth that fails to survive the first year of life.

This problem has been recognized by the World Health Organization, which has recommended that the term "stillbirth" be abandoned, and that all fetal deaths, irrespective of dura-

tion of pregnancy, be registered. Many years will be required before this recommendation can become generally effective since existing legal definitions of stillbirths must be changed and physicians must be convinced of the necessity of reporting every fetal death. It would be visionary to expect that the registration of fetal deaths, especially for pregnancies terminating after only 1 or 2 months, will ever be as complete as the reporting of infant deaths. Nevertheless, the experience in New York City is an illustration of what can be accomplished.

In the meantime, a new measure, the perinatal mortality rate, is beginning to be used. This is computed by dividing the sum of the number of infants dying during the first week or month of life and the number of fetal deaths during the last 4 or 5 months of pregnancy by the number of live births plus the number of fetal deaths included in the numerator.

In addition to the problem of developing a reliable measure of fetal mortality is that of obtaining information concerning the causes of fetal death. This is more complicated and difficult than obtaining information concerning the causes of infant deaths since death may be the result of conditions affecting the mother as well as the fetus. Moreover, medical information concerning the cause of death of fetuses has long been very inadequate. Plans are being made to develop better reporting of the causes of fetal death, but rapid progress should not be expected.

Mortality Rates by Sex

Existing data show that males experience a higher mortality rate from the early months of intra-uterine life until the end of the natural life span. Fragmentary data from genealogical records of ruling families indicate that males experienced higher mortality rates than females as long ago as the 15th century. In some countries and among some classes of the population, mortality rates have been higher for females than for males from about 15 to 30 years of age. This has been particularly true where mortality rates have been relatively high compared with those existing at present. As late as 1925 in the United States, the death rate for ages 15 to 34 years was practically as high for females as for

males. Since then the rate for males has exceeded that for females at every age.

The excess mortality among males has increased as the level of the death rates has fallen. In 1900, the age-adjusted death rate for white males was 10 percent higher than that for white females. By 1950 this difference had increased to 48 percent, and there is no indication that it may decrease in the near future.

The difference between the male and female mortality rates is now large enough to warrant an attempt to discover an explanation. To what extent is it the result of greater occupational hazards experienced by men? How much of the difference may be attributed to biological differences? The ratio of mortality rates for the two sexes is in striking contrast to the ratio of morbidity rates. Although morbidity data are rather inadequate, most studies report higher rates for females than for males.

Mortality During Old Age

Not only has the decline in mortality rates for every age among males in the United States failed to keep pace with the decline in mortality rates among females, but the decline in mortality rates for males more than 40 years of age in the United States also has not kept pace with the corresponding decline for males in most of the countries of northwest Europe, Canada, Australia, and New Zealand. To a lesser extent the same comment applies to the relative decline in death rates among females more than 50 years of age. During the first half of the life span, the mortality rates for males and females in the United States are among the lowest in the world. During the latter half of the life span, the rates for females are near the average of those for similar countries while the rates for males are among the highest of those for similar countries.

Several hypotheses have been advanced to explain this reversal of the relative rank of mortality in the United States during the first half in comparison with that during the second half of the life span but none of these have been adequately tested.

Morbidity

No comprehensive data concerning morbidity for the entire population of the United States

are available. The only extensive morbidity study ever conducted in this country was the National Health Survey of 1935-36, which was a survey of the urban population. Since that time a number of general morbidity surveys of individual communities have been carried out as well as a sample survey for one State but no national study has been undertaken. A few studies of morbidity from specific diseases also have been made.

In 1951 the United States National Committee on Vital and Health Statistics created a subcommittee to study the question of a national morbidity survey and to prepare a plan for such a survey keeping in mind the needs of local areas. The subcommittee recommended that a continuing national morbidity survey be conducted on a scale adequate to provide estimates for 50 regions of the Nation at intervals of 2 years and estimates for the Nation as a whole at 3-month intervals. The survey should be designed to collect information on the incidence and prevalence of diseases, impairments, and injuries, on the duration of any resulting disability, and on the amount and kind of medical care received.

This report (2) was published by the Public

Health Service in October 1953 and subsequently distributed to a number of interested individuals for comment. Although there has been rather widespread endorsement of the desirability of collecting national morbidity statistics, no funds have been available for initiating this work. There is much yet to be learned concerning variation in the frequency of fatal illness among different groups of the population. The frequency of nonfatal illness, however, greatly exceeds that of fatal illness. Our present knowledge of nonfatal illness in the United States is no further advanced than the knowledge of fatal illness at the beginning of the century.

Poliomyelitis Vaccine Injections

The desired levels of immunity in individuals given poliomyelitis vaccine are best derived from the dose schedule in current use, namely, two 1-cc. injections, the second dose 4 to 6 weeks after the initial dose or as soon thereafter as possible, with a booster dose 7 months or more after the second injection.

This was the unanimous opinion of leading virologists and immunologists representing the medical and health professions and the National Foundation for Infantile Paralysis at a meeting called by the Surgeon General on December 7, 1955, to consider how best to use the supply of poliomyelitis vaccine which will be available in the months ahead and to discuss available data on the methods of using the vaccine and spacing of doses. The discussion centered on the possibility of using one injection of 1 cc. in all susceptible individuals before giving the second and the booster injections.

Although it is evident that the injection of 1 cc. of vaccine produces a marked degree of immunity, there is not enough scientific evidence on the duration of immunity after a single dose to lead to any recommendation for a change in the present dosage, the group decided. The Surgeon General accepted the committee's recommendations.

An environmental sanitation problem for the new atomic age may be created by the discharge of radioactive byproducts of nuclear reactions into surface streams. A first anticipatory step is to measure the effects, however slight, of such contamination.

Effects of Low-Level Radioactivity in the Columbia River

By CROSWELL HENDERSON, M.S., GORDON G. ROBECK, M.S.,
and RALPH C. PALANGE, M.S.

THE Public Health Service conducted water quality studies on the Columbia River over a period extending from mid-1951 to mid-1953. Presented here is a brief summary of the general aspects of these studies, followed by a more extended account of the radiobiological phases.

Initiation of Studies

In the accumulation of data to be used for pollution control programs throughout the Nation, it was found that information was needed on the Columbia River from at least two standpoints: (a) for determining the effects

of impoundments, several of which were proposed or under construction, and (b) for determining the effects of radioactive wastes on stream quality.

The construction of impoundments encourages the development of industrial sites, especially where additional power becomes available, and of recreational areas. In semi-arid regions, such as the Columbia River Basin, the increased availability of water for irrigation brings about the development of agricultural areas. Hence, the waters must serve a variety of interests, and in many cases the interests of one group are in conflict with those of another. In order that all interests may be served effectively, basic water quality inventories are necessary.

From the standpoint of the effects of radioactivity, the interests of health, defense, industry, and agriculture were recognized. As the use of radioactive isotopes continues to expand, the responsibility of public health officials for protecting the general population against harmful effects of ionizing radiation will broaden.

The Atomic Energy Commission and the General Electric Co., the present operating contractor at Richland, Wash., have a real interest in using the Columbia River as a source of industrial water supply and also for disposal of

Mr. Henderson is in charge of bioassay application studies, Water Supply and Water Pollution Research Program, Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio. He was staff biologist for the center's Columbia River Studies Unit, 1951-53. Mr. Robeck is assigned to the municipal water supply studies, Water Supply and Water Pollution Research Program, and Mr. Palange is assistant chief of this program. Mr. Robeck and Mr. Palange were, respectively, assistant chief and chief of the Columbia River Studies Unit, 1951-53.

mildly radioactive cooling water from the nuclear reactors. They have, therefore, an understandable concern as to the possible effects of proposed multiple impoundments of the river for irrigation and power projects, lest changes in the characteristics of the stream have an unfavorable influence on plant operations. In addition, the joint interests of the States of Washington and Oregon as to the present and future uses of the river were an important consideration.

A continuous program for controlling the discharge of radioactive wastes to the Columbia River has been in effect since the start of plant operations in 1944. This program, carried out by the operating contractors at the Hanford Works, has included not only the control of waste discharges but also the monitoring of the river within and adjacent to the AEC reservation.

Objectives

The principal objectives of the studies, therefore, were to determine (a) the water quality characteristics of the stream prior to impoundment and (b) the effects of radioactivity on the physical, chemical, and biological characteristics of the stream. The studies also provided data which can be used to establish objectives for comprehensive water pollution control programs. The field work was correlated with the continuous monitoring and research activities of the General Electric Co. at the Hanford Works.

General Procedures

Most of the work was confined to the area between Priest Rapids and Paterson, Wash., a section which includes the Hanford Works and the McNary Reservoir. The latter is an impoundment which was placed in operation in late 1953. Limited studies were also made in Roosevelt Lake, Bonneville Reservoir, and the areas around Portland and Astoria, Oreg., to obtain information on existing impoundments and to determine the persistence of radioactivity to the mouth of the river.

In the Priest Rapids-Paterson section, shown in figure 1, three sampling ranges were

located well above the Hanford plant area to serve as control points. Other ranges in this section were located so as to detect the influence of the plant effluents and other variables, such as tributaries, downstream cities, and impoundments. At each range several types of biological samples were collected in the shallow regions, and water samples were collected at 3 to 10 points across the stream. A mileage index system was used to denote a sampling range or cross section; the designation C-362, for example, indicates a sampling point 362 miles above the mouth of the Columbia River.

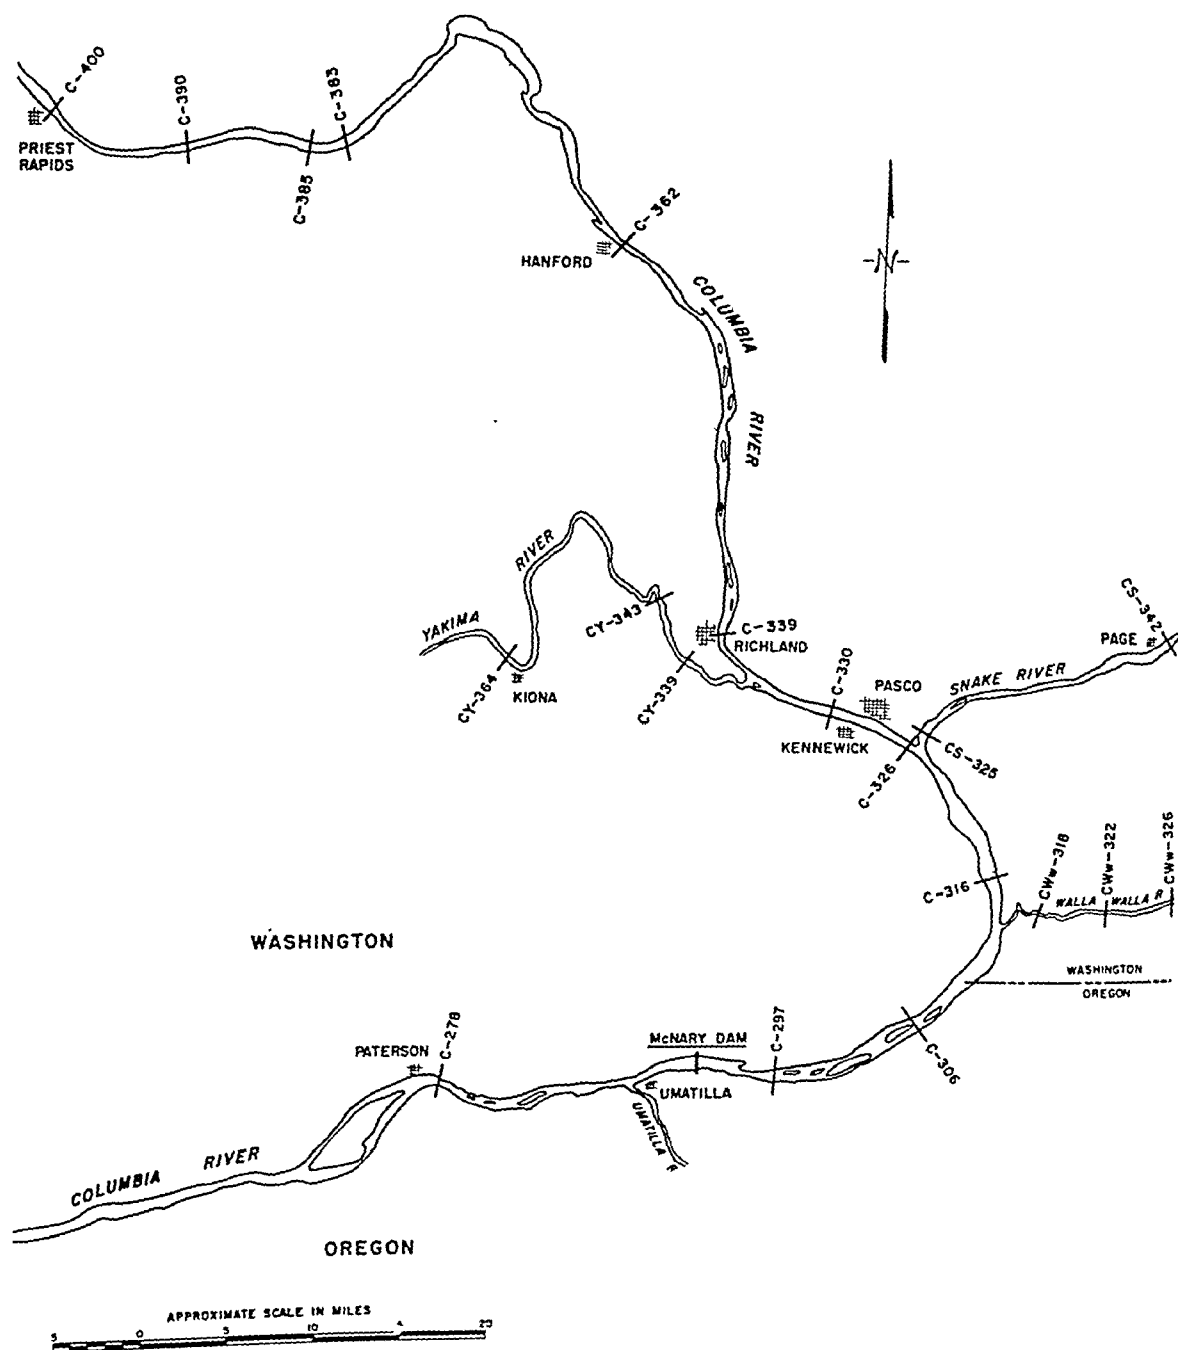

The routine physical and chemical examinations included determinations of turbidity, temperature, dissolved oxygen, ammonia, nitrites, nitrates, phosphates, sulfates, chlorides, pH, and total alkalinity. Mineral analyses were made for the elements considered necessary for plant and animal metabolism, as well as for components which might be toxic. Among these were calcium, magnesium, iron, manganese, zinc, and copper. Bacteriological studies were limited to the determination of coliform MPN.

In the biological studies, quantitative and qualitative samples of plankton, filamentous algae, bottom animals, and fish were collected. The sampling methods were those used in conventional stream surveys. Plankton was quantitatively determined by centrifuging and counting the organisms in a Sedgwick-Rafter counting cell. Bottom animal samples were collected in a square-foot riffle sampler and identified, and the numbers and weights of the various organisms were obtained. Fish were collected in seines and gill nets, and the relative abundance of the various species noted. Observations of spawning activity were made on some species of fish.

Effects on Stream Characteristics

The Hanford plant effluents had no definite measurable effects on any of the physical or chemical characteristics of the Columbia River. Although some of the effluents were thermally hot, the magnitude of the flow in the river was such that there was no general temperature change. On several occasions, slight temperature increases were noted in the area near the

Figure 1. Sampling ranges in the Priest Rapids-Paterson section of the Columbia River, the principal area studied in 1951-53.

effluent outlets. Changes in river flows and the influx of major tributaries did have some effect on the physical and chemical characteristics. However, physical or chemical conditions that would be considered detrimental to aquatic life were not found at any time during the survey.

For many years, the hydrological, physical, and chemical characteristics of the river have followed a definite seasonal pattern. High flows of 300,000 to 400,000 cubic feet per second generally occur between May and July. The most turbid water reaches the Hanford area in

late April or May. During the rest of the year the flow is generally about 50,000 to 60,000 cubic feet per second, and the turbidity is less than 7 p.p.m.

Coliform counts in the Columbia River varied from less than 3.6 to 4,600 MPN per 100 ml. of water. Population centers and tributaries were principally responsible for these variations.

The Hanford plant effluents had little or no effect on numbers and species of river organisms. The variety and abundance of most river organisms were similar above and below the manufacturing areas. Where any differences occurred, they could be attributed to the seasonal variation or the influence of the relatively more turbid, warmer tributaries.

Radiobiological Studies

Although many radioactive wastes and coolants are produced in the manufacture of plutonium at the Hanford plant, the only large effluent to enter the Columbia River directly results from the cooling of the nuclear reactors. The radioactivity is induced by the neutron bombardment of dissolved and suspended materials in the cooling water. The passage of these materials through the atomic pile is held to a minimum by conventional pretreatment of the coolant. The radioisotopes produced in the coolant are principally beta-particle emitters with short half-lives; consequently, retention of the coolant in large open tanks, which provides time for some natural decay, substantially reduces the amount of radioactive material that enters the river.

Water and biological samples, collected weekly or biweekly, were prepared for radiobiological measurement by reducing the sample to a minimum size for insertion into a Geiger-Müller tube, end-window counter. For most solid samples, reduction was accomplished by digesting the organisms in nitric acid and ashing the digestate in a muffle furnace. The residue was then plated on a 1-inch stainless steel planchet and counted for 5 to 15 minutes. The raw count was corrected for decay, geometry, scatter, and absorption, and the results were reported in terms of microcuries per gram of original tissue.

Average Levels of Radioactivity

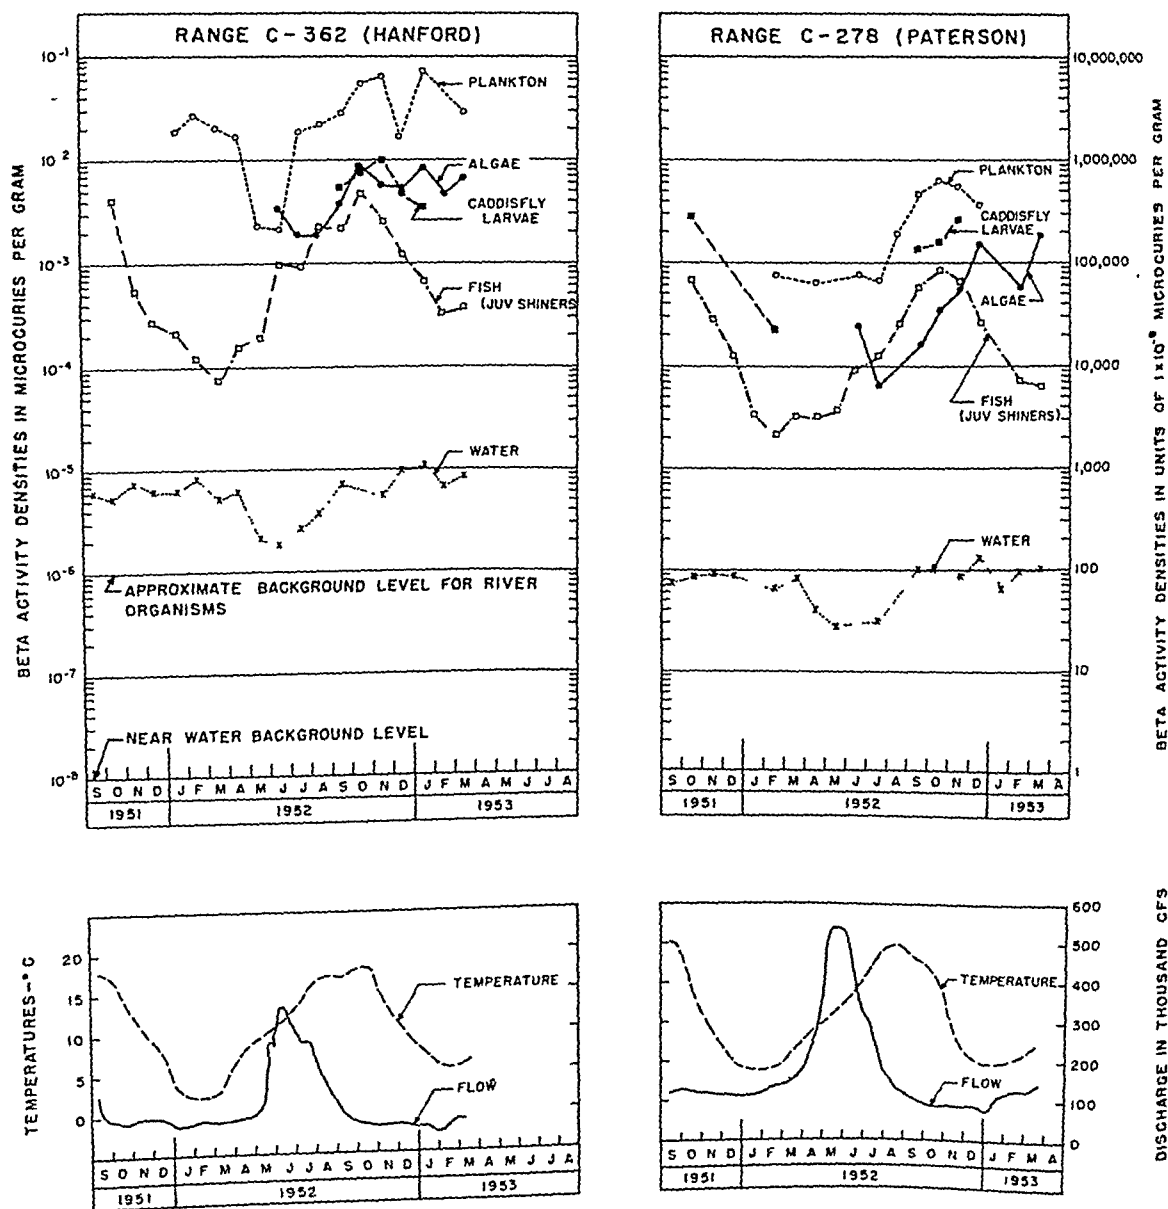

The average gross beta activity density of the water and of the various river organisms (plankton, filamentous algae, caddisfly larvae, and fish) at two of the ranges is given in figure 2. Range C-362, which showed the highest average results, is located just below all nuclear reactors, and range C-278, which showed the lowest average results in the principal study area, is the last range downstream in this section. It is evident from these data that the river organisms concentrate radioactive materials to a considerable degree, up to nearly 10,000 times the total beta activity in the river water. River flows and temperatures at the two ranges are also given in figure 2, for correlation with the radioactivity density.

The accumulation of radioisotopes by aquatic organisms followed a definite pattern. Plankton (mostly phytoplankton) and filamentous algae, which absorb nutrients directly from the water, showed the greatest concentration of radioactive materials. The next greatest concentrations were found in bottom animals, which feed on these organisms; the next, in juvenile fish, which feed principally on the bottom animals. At the end of the chain were the adult game fish, which feed on the juveniles. There were, of course, some deviations from this pattern. Fish that feed directly on plankton and algae reflected higher values in individual samples, whereas crayfish, which possibly feed on dead fish or other animals, reflected lower values.

Levels of radioactivity in plankton and algae were directly dependent upon the radioactivity levels in the water, which were in turn dependent upon river flows and the amount of radioisotopes released into the stream. Values were highest at low water stages, but they were not influenced greatly by changes in water temperature.

Radioactivity levels in most aquatic animals varied with the volume and radioactivity density of the food they consumed. The volume of food consumed depended on their metabolic rate, which in turn depended upon water temperatures. Values for bottom animals were highest at low water stages and high water temperatures. There was a decrease in radioactivity in the organisms with a decrease in water

Figure 2. Seasonal variations in beta activity densities in the water and in various organisms of the Columbia River.

temperature, even though the radioactivity of the materials upon which these animals feed remained relatively high.

The decrease in radioactivity levels with a decrease in water temperature was most marked in fish. Some species, such as bass, which are known to stop feeding when water temperatures are low, showed very low radioactivity levels during the winter months in spite of the fact that there was little or no reduction in the radio-

activity level of the water. The radioactivity levels in these fish rose rapidly with the resumption of conditions conducive to feeding even though radioactivity levels in the water were lower than previously observed because of increased river flows. In other species, such as suckers and whitefish, which evidently feed to some extent even during periods when the water is cold, the reduction in radioactivity was less pronounced. The radioactivity in adult sal-

Figure 3. Gross beta activity densities in water and in various organisms of the Columbia River.

mon, which migrate to this section of the Columbia River from June to October for spawning but do not feed, remained at very low levels.

Resident species which are feeding during this same period contained relatively large amounts of radioactive materials. Apparently, most aquatic animals concentrate radioisotopes of the type encountered in the Columbia River from the food they eat rather than by absorption through the skin or gills.

Types of Radioisotopes

The principal radioisotopes in the river water at range C-362 were such short half-life ones as copper-64 (12.8 hours), manganese-56 (2.6 hours), sodium-24 (15.1 hours), arsenic-76 (26.8 hours), and silicon-31 (2.8 hours). At this range, only about 1 to 2 percent of the

activity was from the longer half-life phosphorus-32 (14.3 days), but at ranges farther downstream this radioisotope became more predominant percentagewise, since the activity from the short half-life radioisotopes had been reduced at a greater rate by natural decay.

The radioisotopes were selectively absorbed or concentrated differently by the various river organisms. Hatchery experiments with trout and salmon (1) have indicated that phosphorus-32 is concentrated in fish principally from food, whereas sodium-24 is absorbed directly from the water. Other radioisotopes may or may not be utilized by the various organisms, but small amounts may be taken into the body in food material.

At range C-362, most of the radioactivity in plankton was due to the short half-life radio-

Figure 4. Variation in average beta activity density in water and fish with location in the Columbia River.

isotopes mentioned previously. The proportion from the somewhat longer half-life phosphorus-32 was relatively small. Some of these short half-life radioisotopes may have been adsorbed on the siliceous diatom shells, which make up a large part of the river plankton. Farther downstream, a larger portion of the activity is caused by phosphorus-32.

The radioactivity in fish and other river animals was primarily from phosphorus-32, even near the areas where nuclear reactors are located. Since the percentage of phosphorus-32 in the water was low, it is evident that this radioisotope was concentrated many thousand times in some river animals. Only a very small part of the radioactivity in any of the river organisms was from radioisotopes with longer half-lives than phosphorus-32.

Variations in Radioactivity Levels

Owing principally to the decay of the relatively short half-life radioisotopes, the gross beta activity density decreased downstream. The activity levels in the river water and in the various river organisms at the different sampling ranges are shown in figure 3. The values decreased rapidly from Hanford (C-362) to Richland (C-339) and somewhat more gradually thereafter, a pattern followed with only slight variations in both the water and the river organisms.

The activity density of adult fish at one sampling range, C-362, is also given in figure 3. The values shown are the highest values for individual parts or organs of each species of fish. The activity density of scales, bones, and internal organs was about 10 times the activity density of the flesh and skin, the edible parts.

The pattern of activity densities in water and fish from Priest Rapids, Wash., to the mouth of the river near Astoria, Oreg., is shown in figure 4. Although some radioactivity is detectable all the way to Astoria, the values are very small in comparison with those found in the Priest Rapids-Paterson section.

The higher radioactivity values found during this survey were from within the Hanford Reservation, but values of similar magnitude have been reported from other areas during a limited period. Values as high as 2.2×10^{-3} $\mu\text{c./gm.}$ have

been found in the muscle of whitefish near Priest Rapids (2).

Other river organisms had gross beta activity densities considerably higher than adult fish, but these organisms are not utilized to any extent by humans. Thus, their major significance is in transmitting this activity to other organisms in the food chain. Fish, as well as ducks, geese, and other animals, may consume these organisms.

As previously pointed out, there were no observable, immediate biological effects on any of the river organisms from radioactivity levels in the Columbia River found during these studies. The genetic changes that may occur in aquatic organisms over a long period were beyond the scope of these studies. Some work on the question of genetic changes is being carried out by the General Electric Co. (3).

Although certain of the radioactivity levels found in the Columbia River organisms appear high when compared to maximum permissible concentrations in the human body, the maximum permissible concentrations for fish and other aquatic organisms have not been definitely established. Some of the work at the University of Washington (4-6) has indicated that the amounts of X-radiation of consequence to certain plankton forms and fish are much larger than quantities permissible for man. The effects of such concentrations in fish eaten by man have not been ascertained.

Public Health Aspects

Because fish and other aquatic organisms concentrate radioactive materials many times above the levels found in water, the use of these organisms for human or animal consumption presents a potential public health problem. Fortunately, most of the radioactivity in fish is from phosphorus-32, a relatively short half-life radioisotope. Natural decay helps in reducing the activity before the fish is eaten. Also, a large portion of the activity is in parts of the fish not used for food, such as scales, bones, and internal organs.

Based on a maximum permissible concentration of 200×10^{-6} $\mu\text{c./ml.}$ and an average daily intake of water of 2,200 ml. (7), the maximum permissible intake of phosphorus-32 for man is

0.44 $\mu\text{c.}$ a day. The average level of radioactivity for the highest 13-week period in the muscle of Columbia River game fish, such as bass, was $100 \times 10^{-6} \mu\text{c./gm.}$, and in Columbia River suckers it was $500 \times 10^{-6} \mu\text{c./gm.}$ Salmon and other migratory species do not appear to be important from the standpoint of ingestion of radioactive materials by man since very little of these materials are concentrated in the adults of the species.

Although the amount of fish flesh that man might eat daily before reaching the maximum permissible ingestion of radioactive materials can be computed on the basis of the results of these studies, such a figure would not be too realistic. Few, if any, humans would eat the indicated quantity of fish daily over a lifetime. Moreover, the fish are not eaten immediately after being caught, some time being required for cleaning, cooking, and other preparation. Thus, the actual permissible intake would be greater than the figure computed.

Conclusions

The following major conclusions regarding radioactivity in the Columbia River are drawn from the Public Health Service studies of 1951-53:

1. Low-level beta activity has had no adverse effect upon the numbers and species of aquatic organisms in the Columbia River.

2. The radioactivity levels in plankton and attached algae are directly dependent upon levels in the river water.

3. The radioactivity levels in aquatic animals vary with their metabolic rates (which in turn vary with water temperatures) and with the radioactivity levels of the materials upon which they feed.

4. Migratory species in the Columbia River such as salmon, the adults of which do not feed in fresh waters, have low radioactivity levels at the same time that levels in resident species are high.

5. Radioactive materials are concentrated in all parts of the body of the fish. The activity

levels, however, are about 10 times higher in scales, bones, and internal organs than in the edible parts, such as muscle and skin.

6. Since aquatic organisms concentrate specific radioisotopes such as phosphorus-32 many thousand times above the levels in water, the use of these organisms for human or animal consumption presents a potential public health problem. However, to date the levels of radioactivity in the flesh of Columbia River fish are not dangerously high.

New York State used the home interview technique to gather data for determining accident rates for a sample of motor vehicle drivers in Saratoga Springs. From this preliminary study, we learn that it is possible—if the data are sufficient and the population is well defined—to obtain reliable rates on which to base future accident prevention activities.

An Epidemiological Approach to Traffic Accidents

By WILLIAM G. BEADENKOPF, M.D., M.P.H., ADELE K. POLAN, M.A., WALTER E. BOEK, Ph.D.,
ROBERT F. KORNS, M.D., Dr.P.H., and GEORGE JAMES, M.D., M.P.H.

MOST traffic accidents are apparently due to errors in the decisions of drivers rather than to defects in the motor vehicle or hazards present on the road. It has been estimated from analyses of accident reports that 75 to 90 percent of all traffic accidents can be attributed to human error (1). Although acci-

dent report data are admittedly not entirely reliable, particularly with regard to the designation of human error as the responsible factor, it remains likely that some large portion of automobile accidents result from miscalculation by the driver.

Dr. Beadenkopf is assistant director, bureau of epidemiology and communicable disease control, New York State Department of Health. Dr. Korns was director of the bureau at the time of the study and is now assistant commissioner of the department's office of development and evaluation. The former assistant commissioner of this office, Dr. James, is now director of health, Akron (Ohio) Department of Public Health. Both Mrs. Polan and Dr. Boek are also with the New York State Health Department, as biostatistician and research anthropologist, respectively.

This report was presented in part at the Second Highway Safety Research Correlation Conference on Health, Medical, and Drug Factors in Highway Safety, Washington, D. C., April 1954. The conference was sponsored by the Committee on Highway Safety Research of the National Academy of Sciences-National Research Council.

There is considerable evidence which suggests that several characteristics of the driver are associated with a high risk of involvement in the accident. Persons with high levels of alcohol in the blood have been found to be involved in accidents more frequently than those without such levels of alcohol (2, 3). Individuals who become involved in accidents repeatedly have been characterized as accident prone although the permanence of this characterization is uncertain (4). A variety of driver selection studies by commercial and military agencies have tested intelligence, speed and accuracy of perception, learning of coordination, and certain attitudes (1). When accident reports from general populations are analyzed according to age, it has been found that young persons between 18 and 25 have a disproportionately high number of accidents (5).

To Identify the Hazardous Driver

The many procedures that have been employed have met with varying success in the

attempt to identify individuals with a greater likelihood of becoming involved in accidents. The aim common to all such efforts is to identify the hazardous driver in order to exclude him from the driver population, at least until he has been successfully retrained. With few exceptions, however, the evidence supporting these means for detecting hazardous drivers has apparently not been sufficiently convincing to warrant general acceptance as screening procedures by official agencies charged with licensing drivers. This lack of acceptance may be due in part to the nature of the attributes chosen for study or to the particular methodology of the study. Whatever the reason, the result has been that the findings cannot easily be applied to the general population.

The New York State Department of Health thought it worth while to attempt to apply the epidemiological approach to a study of traffic accidents. Consultations with traffic authorities lent encouragement to the plan and also provided essential technical advice. Close sociologic supervision was supplied throughout

all stages of the planning and operation of the study. Special attention was given to interviewing techniques and sampling of the population.

The epidemiological method consists essentially, first, of grouping the members of a general population according to well-defined characteristics, such as age, sex, occupation, and, where possible, exposure to the event or disease under study; and, second, of determining the proportion of the groups that experiences the event or becomes ill. This information is useful in order to determine how a disease starts or where it exists in a community, how it spreads, and where control measures should be applied.

The epidemiological approach has proved of value in the control of many diseases—occupational diseases are an example. An epidemiological study, therefore, of certain attributes of the driving population of a community holds promise for ascertaining whether the traffic accident problem is in reality largely one of human behavior.

Figure 1. Proportion of adult population who are drivers, according to age and sex.

Figure 2. Exposure to traffic accidents in terms of the median miles driven during preceding year, according to age and sex.

This report presents some of the data obtained in the health department's exploratory study in traffic accident epidemiology. In the hope of stimulating critical interest, illustrations of some of the techniques that were employed are presented in the form of graphs or tabulations.

The Sampling Techniques

Our investigation was made during a 3-week period of clear weather in late November and early December 1953 at Saratoga Springs, N. Y. The population studied consisted of a sample carefully selected in the hope that it would be representative of the city and the surrounding natural trading area, a zone of approximately 5 miles. The sampling procedure was one of assigning consecutive numbers to all blocks on a map of the city and to all segments of the rural area, and, then, by reference to a table of random numbers, of choosing

a sample of blocks and segments to be studied. Every fourth household of each sample block or segment was assigned for interviewing.

An attempt was made to interview all individuals 15 years and older in the study population. Children under 15 were enumerated only. Interviews were successfully obtained with 563 of the 637 individuals in the study group but not with 74 persons, most of whom were not at home on repeated visits. Seventeen declined to be questioned. The 74 individuals who fell in our theoretical sample, but who were never interviewed, do not form a part of the study population.

The interviewing was handled by 9 biostatisticians, 2 physicians, and 1 cultural anthropologist, all from the health department. Twenty-nine sociology students at Skidmore College assisted. To assure consistency in the use of interview techniques, each interviewer was given several hours of training. Interview questions had been pretested in the city of

Motor vehicle bureau file alone.....	6	-----	-----	5	1

Oneonta with the assistance of sociology students in the Oneonta State Teachers College.

Information was sought on a variety of subjects that can be described briefly as identifying information, exposure to traffic accidents, driving experience in number of years of driving, description of automobile trips on the day before the interview, health status, income, occupation, involvement in a traffic accident occurring earlier in 1953, and some opinions on the driving regulations and traffic problems of Saratoga Springs.

Some of the Findings

Examination was made of the study population by age and sex, according to whether or not the respondent drove a motor vehicle. In all age groups a considerably larger proportion of men than women are drivers, it was found. This finding is illustrated in figure 1, which also shows a steady decline in the proportion of drivers with increase in age. Of the persons interviewed, 264 were men and 299 were women. Seventy-eight percent (205) of the men and 42.5 percent (128) of the women were drivers.

Exposure to traffic accidents was determined in terms of the number of miles that the individual stated he had driven during the preceding months in 1953. The variations in exposure by age and sex are shown in figure 2.

The median number of miles driven per year varies from 1,200 miles (women, 21-24) to more than 13,000 miles (men, 21-29). It can be seen from the figure that the line for women is consistently below that for men, although several points on the curve are based on only a few observations.

Twenty-five members of the study population had been involved in automobile accidents during the 11-month period between January 1 and

NOTE: Number of miles has been rounded off to nearest hundred. Accident rates were calculated from original figures.

Figure 3. Stated usual speed on open road.

(approximately) December 1, 1953. Data on the number of accident-involved persons and the severity of the accidents are presented in table 1. No distinction was made by our investigators between persons to blame or not to blame for their accidents, nor was the definition of a traffic accident elaborated on in any great detail.

The information about accidents was gathered from two sources: the interview and the New York State Bureau of Motor Vehicles.

In the interview the question was asked, "Have you by any chance been involved in an accident since January 1 of this year? I would like to know about all accidents regardless of whether or not it was your fault or how small it was." The respondent himself was depended on to determine what constituted a motor vehicle accident.

Search of the accident file of the bureau of motor vehicles over the 12-month period Janu-

ary 1 to December 31, 1953, corroborated 10 of the accidents reported by the respondents. However, six reports were found in the bureau file for accidents that were not reported during the interviews. Nine persons stated that they had been in accidents, but reports for these accidents were not found in the bureau file.

A portion of these individuals may have had accidents which occurred outside New York State or accidents which involved no other car. Some also were too minor to report on legal grounds since New York State law requires that reports be filed only for an accident that involves personal injury or property damage over \$50. Details were not obtained about the accident during the interview, and, therefore, it is not possible to estimate the severity of the latter group of accidents. We did not expect to obtain as many accidents as we did from the interviews. We anticipated that the severity could be better measured by the official reports.

Accident rates are presented (table 2) according to age, sex, and exposure. In order to derive the rate, the median number of miles driven during the year of exposure (column *a*) was multiplied by the number of drivers in each age group (column *b*). The product (column *c*) represents the total exposure for an age group. The number of accident-involved persons (column *d*) is divided by the total exposure

(column *c*) to obtain the accident rate per million miles of exposure (column *e*).

The limited size of the study material, as reflected in the small number of accidents, makes for unstable rates. This instability is especially apparent in the rates shown for women drivers. However, there is a suggestion in the data that men aged 25 to 59 experience lower accident rates than men of other ages.

Saturday.....	16	10	62.5	32.9

The sharp difference in the number of miles driven by men and women is also brought out in table 2. By comparing column *a* with column *f*, we see that a man drives approximately four times as much as a woman. Coupled with this difference is the additional fact that there are more men drivers than women drivers, as shown in figure 1. Thus, for every mile driven by a woman (column *h*), there are 6 miles driven by a man (column *c*).

Some Additional Characteristics

The home interviews produced a variety of additional data. Much of this information would prove useful for further identification of hazardous drivers if the quantity of study material permitted. Several characteristics of drivers are presented (fig. 3 and table 3), to illustrate how a particular age and sex group with a high accident rate could be further analyzed according to such factors as drinking, habitual rural or urban driving, opinion on speed limits, usual speed of driving.

One of these characteristics, the usual speed driven, is diagramed in figure 3. Speeds that respondents said they usually drove on the open highway are plotted against age for both sexes. The line, in the figure, for women lies under the line for men in all age groups below age 65. By designating the 25 accident-involved individuals as *x* and *o* (*x* for men, *o* for women) on the diagram, we can see that accidents are distributed about equally above and below the median speeds. This distribution suggests that

high-speed drivers and low-speed drivers experience a similar number of accidents. However, it should be pointed out that correcting the data for driving exposure and for the factor of the reliability of the statements on speed would provide a more accurate interpretation.

Examples of additional characteristics are shown in table 3. These topics presented no insurmountable problems in most of the interviews. Responses were usually given freely, with an effort to be accurate, to such delicate questions as drinking, income, previous driver license suspension—not shown in the table, but license suspension was admitted by 10 persons. The determination of income by interview of a sample in a population has been employed successfully, of course, in numerous sociologic surveys. Several questions were asked about the presence of a chronic disease or a disability—not included in the table either—but the small base population did not yield many individuals so afflicted.

Some examples of the activities which the drivers reported for the day before their interview are examined in tables 4–6. The question as to what trips were made yesterday (table 4), a query frequently used in origin-destination surveys, has been successfully applied to the analysis of traffic flow for the design of traffic arteries (6). A group of individuals identified as those who drank before driving was compared with a group who did not drive after drinking (table 5). The time of drinking was compared with the time of driving on that day, about which inquiry had been made earlier in the interview. From the inquiry about medications taken on the day before inter-

Table 5. Alcohol consumption on day before interview

No medication-----	284	192	81.7	92	82.9

view (table 6), it is of interest that no substantial decrease in driving was observed for the 35 persons who took some type of medicine.

Many additional analyses were attempted of variables of interest in highway safety. Some of these analyses included these characteristics: speed by family income groups, number of trips made and number of passengers carried on day before interview, frequency of driving, time of driving, and stated usual speed on open road according to occupation. More extensive investigation is required to yield reliable information on these factors.

Validation of the Findings

Some characteristics of the study population were compared with those described for the Saratoga Springs area by the 1950 national census in order to see whether the sample studied was truly representative of the community. Close similarity between the sample and the actual population was found in the proportion of men and women, of nonwhites, and of individuals in gross age groupings, household size, occupation, and family income. In the inquiry about occupation, sufficient details were not obtained to permit classification of a professional driver group since the emphasis was placed upon a classification that could be compared with census data.

In an effort to measure validity, the results of the inquiry about age and driver status have been compared with data from another source. A comparison is shown in table 7 of the ages of drivers interviewed in the study and the ages of drivers licensed in upstate New York. The close similarity in the age structure of the two populations serves as evidence for reliability of the sampling and interviewing procedures employed in this study.

The accident rates computed for the data shown in table 3 are intended to illustrate method and cannot be considered stable. The stability of the computed rates was examined by determining the variation that exists in a random subgrouping of the sample. Rates were computed for subgroups according to their household numbers. Variation in rates among the subgroups was found to equal or exceed many of those in the data presented.

Validation of responses on each of the interview topics (table 3) is highly desirable before any inferences are to be drawn and should be done wherever possible in larger samples that may be studied. The validity of responses

Table 7. Composition of driving population in regard to age and sex and in comparison with a 1952 sample of licenses in the New York State Bureau of Motor Vehicles¹

² The age groups 15-24 years include 8 drivers without any license.

should be tested especially for the desire of the respondent to be accurate and his ability to supply accurate estimates of rather complex activities. The estimate of the number of miles driven during the preceding months in 1953 (fig. 2), for example, was difficult to determine for some individuals, particularly for some professional drivers and some housewives. Reliability and accuracy of the responses regarding exposure require further study.

The validity of the estimates of exposure that have been employed in the calculation of accident rates is of special interest. In the inquiry about the driving reported for the day before interview (table 4), approximately two-thirds (67.9 percent) of the drivers had driven an average of 34 miles on the day preceding their questioning. Variations are shown in the proportion of drivers who drove and in the mean number of miles driven according to the day of the week.

The number (33.9) of mean daily miles driven is in close agreement with the estimated annual exposure of 7,750 miles for the members of the study population (this estimate was determined from the data presented graphically in figure 2) and compares well with the national average of 7,800 miles estimated for 1953 (7).

The agreement can be demonstrated in this fashion: If 33.9 miles are driven daily by 67.9 percent of the study population, then the entire group of drivers drives an average 23 miles a day. Multiplying 23 by 365 (the number of days in a year) yields approximately 8,400 miles for an estimated year of driving.

Discussion of Values

The foregoing material illustrates methods for gathering and assaying epidemiological data about selected characteristics of automobile drivers that may be of importance in contributing to traffic accidents. The data also serve as a basis for estimating the amount of study material needed to determine reliable accident rates according to relatively well-defined characteristics in the general population. On the basis of these preliminary results, we consider the epidemiological approach applicable to a study of traffic accidents.

The validity of several steps in the application of the method to traffic accidents has been reviewed. To summarize briefly, the sampling procedures employed yielded a population whose attributes were comparable with those described in the 1950 census and also were comparable, with respect to age, to a sample of driver licenses issued by the State bureau of motor vehicles. Inquiry concerning exposure to traffic accidents was found to yield results comparable with data from other sources.

In addition to serving as an illustration of the epidemiological method, some points in this report mark out unequivocal differences in driving experience and exposure in the general population. Almost twice as many men (78 percent) as women (42 percent) drive an automobile. The exposure to traffic accidents in number of miles driven per year for men is approximately 6 times that for women. Marked age-sex differences are seen, both in the proportion of drivers and the amount of annual driving done in a year. Such variations as these offer strong argument for a critical examination of various groups within the driving population as one phase in the search for hazardous drivers.

A measure of the reliability of obtaining accident reports in interviews is apparent from the data shown in table 1. Only some two-thirds of the individuals questioned related the story of accidents that they had previously reported at the time of accident. This measure of agreement represents a lower degree of reliability for interview material on the subject of an accident than that encountered on such topics as exposure and occupation. Improvements in interviewing techniques might increase the yield from this source.

It is not essential, however, to obtain information on an accident from the respondent in the interview so long as official machinery exists for this purpose. Accident reports on file in the bureau of motor vehicles can serve as the sole source for the numerator. Computing accident rates from this secondary but official source should introduce no crucial bias. The study sample, of course, should be of sufficient

size to compensate for the proportion of accidents learned at interview only.

Deserving of mention is the encouraging frankness encountered during the interviews on subject matter ordinarily considered touchy. Information was voluntarily given by most individuals on the matter of drinking, speeding, license suspension, and, in spite of the fact that the interviews were for an automobile accident study, on various physical disabilities and chronic diseases.

A few individuals interviewed did not state their age; a few did not state exposure. Thirteen men and 35 women did not state the number of miles driven. These omissions, which account for the variations in the study population from table to table and chart to chart, result from two factors: The omissions were not discovered soon enough after the interview to be rectified, and the question on exposure was apparently a difficult one for some persons to answer accurately. Interview techniques and questions especially developed to arrive at the estimate of exposure would help respondents supply an accurate figure.

We recognize that information on accident rates related to fairly well defined, stable characteristics may be rewarding for only a portion of accidents. Many accidents may be more closely related to very fleeting human attributes such as temporary emotional tensions. These, of course, present special, complex problems for study and validation.

If we had studies based on populations of suitable size, we could look for answers to such questions as: To what age group among the general population should special efforts be directed with regard to the screening and retraining of automobile drivers who have had accidents? What is the part of the physically impaired person in the accident problem? Of the deaf individual? The intoxicated driver? The habitual speeder? The slow driver?

We have shown that the epidemiological method of evaluating certain characteristics of drivers and other important aspects of the traffic problem can be expected to provide critical results expressed in convincing accident rates. As a result, the New York State Health Department has been sufficiently encouraged to plan a traffic investigation, greater in scope

than the Saratoga Springs study, in collaboration with other agencies concerned with the problems of traffic safety.

Two refinements not employed in the Saratoga Springs study will be made in future attempts to define accident-involved individuals. First, accidents that are manifestly the result of the operation of a defective vehicle or of an environmental hazard will be excluded from consideration in those instances where the judgment of the driver is not involved. Second, responsibility for an accident may be fixed for a group of individuals in order to define the accident-susceptible individuals more accurately.

Summary

A method for determining motor vehicle accident rates for groups within a general population has been tested in a preliminary manner by means of home interviews of a sample in a New York State community. It is suggested that, given sufficient data, accident rates can be determined for well-defined population groups which would assist considerably in providing direction and impulse for accident prevention activities.

The State of the Nation's

public
health
services

Abridged reports from the 54th Conference of the Surgeon General of the Public Health Service and the Chief of the Children's Bureau with the Association of State and Territorial Health Officers, the State Mental Health Authorities, and the State Hospital and Medical Facilities Survey and Construction Authorities, November 6-12, 1955, Washington, D. C.

Opportunities For Nationwide Cooperation

I By Marion B. Folsom
Secretary of
Health, Education, and Welfare

This is my first opportunity to meet with a group of State officials whose work is closely connected with the work of the Department of Health, Education, and Welfare. It is an opportunity I deeply welcome. I know the

kind of wisdom and experience and integrity you bring to the advancement of public health. And I know the value of meetings of this type, where people may work on common problems, exchange knowledge, and perhaps come up with new ideas for progress.

It is evident that the greatest progress is made in public health when there is closest cooperation between local, State, and Federal officials. Coordination with State health officers is essential if the Federal Government is to do its part effectively. State health officers are close to public health needs and problems. They know at first hand what resources are available. For these reasons, and others, your advice is especially valuable in the early planning stages of any nationwide public health program.

size to compensate for the proportion of accidents learned at interview only.

Deserving of mention is the encouraging frankness encountered during the interviews on subject matter ordinarily considered touchy. Information was voluntarily given by most individuals on the matter of drinking, speeding, license suspension, and, in spite of the fact that the interviews were for an automobile accident study, on various physical disabilities and chronic diseases.

A few individuals interviewed did not state their age; a few did not state exposure. Thirteen men and 35 women did not state the number of miles driven. These omissions, which account for the variations in the study population from table to table and chart to chart, result from two factors: The omissions were not discovered soon enough after the interview to be rectified, and the question on exposure was apparently a difficult one for some persons to answer accurately. Interview techniques and questions especially developed to arrive at the estimate of exposure would help respondents supply an accurate figure.

We recognize that information on accident rates related to fairly well defined, stable characteristics may be rewarding for only a portion of accidents. Many accidents may be more closely related to very fleeting human attributes such as temporary emotional tensions. These, of course, present special, complex problems for study and validation.

If we had studies based on populations of suitable size, we could look for answers to such questions as: To what age group among the general population should special efforts be directed with regard to the screening and retraining of automobile drivers who have had accidents? What is the part of the physically impaired person in the accident problem? Of the deaf individual? The intoxicated driver? The habitual speeder? The slow driver?

We have shown that the epidemiological method of evaluating certain characteristics of drivers and other important aspects of the traffic problem can be expected to provide critical results expressed in convincing accident rates. As a result, the New York State Health Department has been sufficiently encouraged to plan a traffic investigation, greater in scope

than the Saratoga Springs study, in collaboration with other agencies concerned with the problems of traffic safety.

Two refinements not employed in the Saratoga Springs study will be made in future attempts to define accident-involved individuals. First, accidents that are manifestly the result of the operation of a defective vehicle or of an environmental hazard will be excluded from consideration in those instances where the judgment of the driver is not involved. Second, responsibility for an accident may be fixed for a group of individuals in order to define the accident-susceptible individuals more accurately.

Summary

A method for determining motor vehicle accident rates for groups within a general population has been tested in a preliminary manner by means of home interviews of a sample in a New York State community. It is suggested that, given sufficient data, accident rates can be determined for well-defined population groups which would assist considerably in providing direction and impulse for accident prevention activities.

The State of the Nation's

public
health
services

Abridged reports from the 54th Conference of the Surgeon General of the Public Health Service and the Chief of the Children's Bureau with the Association of State and Territorial Health Officers, the State Mental Health Authorities, and the State Hospital and Medical Facilities Survey and Construction Authorities, November 6-12, 1955, Washington, D. C.

Opportunities For Nationwide Cooperation

1 By Marion B. Folsom
Secretary of
Health, Education, and Welfare

This is my first opportunity to meet with a group of State officials whose work is closely connected with the work of the Department of Health, Education, and Welfare. It is an opportunity I deeply welcome. I know the

kind of wisdom and experience and integrity you bring to the advancement of public health. And I know the value of meetings of this type, where people may work on common problems, exchange knowledge, and perhaps come up with new ideas for progress.

It is evident that the greatest progress is made in public health when there is closest cooperation between local, State, and Federal officials. Coordination with State health officers is essential if the Federal Government is to do its part effectively. State health officers are close to public health needs and problems. They know at first hand what resources are available. For these reasons, and others, your advice is especially valuable in the early planning stages of any nationwide public health program.

The public health grant program is one of the fields which presents an opportunity for cooperation to provide better health services. Grants-in-aid are extremely useful tools, and like other tools, they need to be improved and modernized from time to time to meet changed conditions and to be more flexible in meeting the needs of each State and Territory.

Just as our programs must keep pace with growth and change, so must our staffs in public health agencies. Yet today, when the potential benefits of public health services are greater than ever before, many State and local health departments are hampered by shortages of trained personnel. Health officers can do much to help solve this problem, as you recognize. There is, for example, an obligation to make more training available to those already on the job. There is also general agreement that the Federal Government has a responsibility in this field. In addition to the programs for traineeships in public health and for increased training of nurses which are proposed, I would welcome suggestions and recommendations from this group as to other ways in which the Department can be helpful.

Now, a word about the allocation plan for poliomyelitis vaccine. It has been, from the beginning, a good example of the type of State and Federal partnership that makes for progress. The executive committee of the State and Territorial Health Officers Association was represented at all the early planning conferences. It played an important role in the development of a workable system of voluntary controls.

Currently, we are depending on State health departments for detailed information and an analysis of the vaccine's performance. This is part of an evaluation of the vaccine's effectiveness which will be made by the Public Health Service's Poliomyelitis Surveillance Unit in Atlanta. Already we have preliminary reports from 11 States covering almost 5 million children. The scientists say these reports indicate the rate of paralytic poliomyelitis was reduced about 75 percent among vaccinated children, as compared with unvaccinated children in the same age groups.

The poliomyelitis vaccination program is an example of widespread application of new

medical knowledge. In the 8 months since the effectiveness of the vaccine was first announced and was licensed for general use, the Public Health Service has released enough vaccine to give 2 injections each to more than 12 million children.

Out at the National Institutes of Health, at other Public Health Service laboratories, and through the research grants program, we are searching for answers to the other cripples and great killers. We still have much to learn about cancer, mental illness, and heart disease. There are possibilities for great benefits to humanity through more research.

It is equally true, however, that we are not yet fully applying the knowledge we already possess. Much more can be done now to prevent disease, to mitigate its disabling effects, and to rehabilitate its victims. Finding ways to do these things, of course, is not easy. There are fiscal problems, personnel problems, problems of public understanding and acceptance, to mention only a few.

But we do share the important essentials—agreement on goals, on principles, and on the ways of working together. We have every reason, therefore, to make steady progress.

In this spirit, I wish you well in the important work you are doing and pledge you all the help that we in the Department are able to give.

The Wide Spectrum Of Our Health Services

2 By Leonard A. Scheele, M.D.
Surgeon General of the
Public Health Service

In his monograph, "The Cost of Sickness and the Price of Health," published by the World Health Organization, Dr. C.-E. A. Winslow writes:

"Progress made in the public-health sciences during the past half century has made it clear

that the heavy burdens of disease can, in large measure, be lifted by the application of scientific knowledge already available; and each year the results of public-health research are broadening the area of possible control."

To most health workers in this country, this statement may seem to be "old hat." We say it again and again—to ourselves, to our colleagues in public health and medicine, to our law-making and appropriating bodies, to our superiors wherever we work, and to the citizens we serve. But we must not allow repetition to dull our senses.

In this country especially, we must keep ourselves keenly sensitive to the "broadening area of possible control." We have gone far in the application of knowledge to the control of diseases which formerly imposed enormous burdens on our people. Some of us here have been in public health work long enough to have witnessed the spectacular decline and virtual disappearance of some of these diseases in our country. Typhoid fever, diphtheria, smallpox, yellow fever, malaria, pellagra, hookworm: the list is long, the accomplishment great.

Success has its perils, however; and one of the most insidious is that our very accomplishments can dazzle us to the point of blindness: blindness to the fact that "each year the results of public health research are broadening the area of possible control." Each year, mind you.

If we are not alert to these rapid advances, if we are not ready and willing to apply the new knowledge as earnestly as we applied the old, we may soon find that we are behind even in our application of "available" knowledge and that public health science again is way ahead of us.

Some health administrators may feel that our major problems today will not yield to the same type of attack that has been suitable for communicable disease control. But we have proof that the public health approach can be equally effective elsewhere. The dramatic reductions in maternal and infant mortality required new specific techniques, but the broad public health approach was the same. Severe nutritional deficiencies, such as pellagra, have yielded to public health attack.

We should recall, also, that our predecessors did not wait for the perfect control techniques against infectious diseases. With enthusiasm and determination, they set out and applied what they had.

Some of the tools they used at first—and used with considerable effect—would no doubt be rejected by public health workers today as too crude, too difficult to apply, too costly, or not effective enough. Subsequently, high precision tools of remarkable specificity were developed for the prevention of some infectious diseases. It may be that this high precision in one field of public health effort has made some of us overly fastidious in our consideration of less specific techniques now being brought forward as possible means of attacking numerous major health problems of the present era.

There is certainly a tendency to be skeptical about or reluctant to the intensive application of new knowledge in some areas—especially if application involves change in our traditional patterns of thought and public health organization.

A few years ago, for example, I stated that improved techniques of case finding and the availability of streptomycin and para-aminosalicylic acid placed health agencies in a position to wage a new offensive campaign against tuberculosis. I said that within a generation, we could reduce tuberculosis to a minor cause of death and disability in the United States. The reaction of some health workers to that statement was skeptical. Fortunately, many others agreed. Since then, the advent of isoniazid has brought my earlier prediction closer to realization.

Our health agencies must not refuse to accept the new life-saving promises of science. The American people do accept those promises. And they will find ways to bring about their fulfillment, even if it means creating new agencies in our States and cities, because their health departments have become enmeshed in their traditional programs and are not ready to move ahead.

The American people have given their health agencies ample evidence of their enthusiasm and acceptance. They are supporting health programs with tax funds and personal donations to a greater extent than ever before. They

are not concerned, however, with the perpetuation of nonproductive enterprises. They are patient—sometimes too patient—but in the long run, they will support only those organizations that are trying to help them meet the problems that most concern them.

Finding Community Needs

We in public health are inclined to take a "mother-knows-best" attitude toward our communities in determining what those critical problems are, and in deciding which services shall be developed. For official health agencies, this attitude is natural to a certain extent, since State and local health departments have long had the legal responsibility to keep track of sickness and death, and they are supposed to know what the problems are and how to solve them. In the voluntary agency, decisions with respect to services are naturally made by leaders who are personally concerned with the specific objectives of the agency. But the official and voluntary health leaders comprise a very small part of the community. Thus, health agencies need to find ways of drawing the public closer in the process of determining issues that affect the whole community.

We would like to think, for example, that "health" has as high priority for the entire adult population as it has for us. Preliminary interviews of a small group in one community showed that the only adults who gave "health" first priority were those who have children, or have been ill recently themselves, or have a relative with long-term illness. Actually, these people comprised only 20 percent of all persons interviewed.

In seeking guides to the public's health needs, a fresh look at our mortality and morbidity data might be enlightening. Dr. Selwyn D. Collins and his co-workers, in the Public Health Service, have recently published a provocative document: *Major Causes of Illness of Various Severities and Major Causes of Death in Six Age Periods of Life*. The study is based on five Public Health Service surveys of illness, dating back to 1928.

Here are a few of the revelations in this recent review of our Nation's health status.

Serious mental disease, mental deficiency, and

neurological disorders account for the highest disability rates in one of those supposedly "healthiest" age groups, our school children, 5 to 14 years of age. The same diseases account for the highest rates in youth (15-24), young adults (25-44), and the middle aged (45-64).

Although diseases of the heart are the first causes of death in each age group from age 25 onward, they do not account for serious disability rates until age 45 years and over.

Many health agencies have apparently lost interest in influenza and pneumonia, the common cold and other minor respiratory ailments. The Conference of State and Territorial Health Officers, for example, has adopted only two recommendations on any of these infections for nearly two decades; and these were with respect to influenza virus studies. Yet in frequency, these diseases outrank all other causes of disabling illness in every age group, from birth to old age. In old age, influenza is exceeded only by diseases of the heart in frequency of disabling cases and bed cases. It is significant too that for children under 15 the first cause of hospital admissions is tonsillectomy, a surgical procedure commonly recommended as a result of respiratory infections.

Dr. Collins writes: "Death has no time dimension; even if the duration of the last illness is tabulated, the data on the death certificate give no idea of the frequency or extent of the many nonfatal illnesses that may have preceded the final illness." I would add that not only are the death certificates mute, but science is also silent about the relation of our lifetime experience with nonfatal illnesses to the occurrence of the final illness.

There is great research interest in these problems today; many stimulating studies are being conducted that may give some answers. Whatever the answers may be, it is clear that the basic principle of public health—prevention—can reduce substantially the assaults of nonfatal illness, if we do but apply this principle wherever science has given us techniques and wherever there is an opportunity.

A Challenging Era

We in public health have demonstrated that massive attacks on specific diseases will pro-

duce results. A massive attack requires a massing of resources: funds, personnel, equipment, materials, and facilities. When the public has been strongly motivated to provide this massing of resources, then prevention, control, and, eventually, eradication can follow. In the chronic illnesses of later life, some prevention and considerable extension of life can be accomplished in a massive attack.

The poliomyelitis vaccination program is the most recent example of what can be done when strong interest and an adequate budget permit a concentrated attack on a preventable disease. A voluntary health agency has had the magnificent courage to channel the public's emotional drive against poliomyelitis into the research and development of the first effective preventive vaccine for paralytic poliomyelitis. The public, thus strongly motivated, has made possible through their representatives in Congress a nationwide program that will not only attack poliomyelitis, but will also strengthen State and local health agencies in basic skills to deal with other viral diseases.

A similar massing of resources in our States and communities could speed the eradication of some diseases which are already declining rapidly and could bring about substantial reductions in deaths and illnesses due to diseases which have shown few signs of retreat.

For example, there is hope for chemoprophylaxis of tuberculosis. The tuberculosis research staff of the Public Health Service has demonstrated that oral isoniazid, administered daily, is effective in preventing tuberculosis in experimental animals. Clinical trials with isoniazid have been initiated for the prevention of tuberculous meningitis and other complications in newly infected children. Twenty-five pediatric centers are cooperating with the Public Health Service and the National Tuberculosis Association in the first large-scale, controlled study using an antimicrobial drug as a prophylactic agent against tuberculosis.

The effectiveness of isoniazid as a general preventive of tuberculosis depends on the outcome of this study and on controlled trials in other and larger population groups. Persons who react positively to tuberculin and persons who exhibit suspicious shadows on X-ray films may be the first to benefit from the preventive

and curative properties of isoniazid. The drug can be produced easily in large quantities at a very low cost.

Definitive treatment of tuberculosis can now be administered by the private physician to the patient at home or in the clinic, but with home treatment great care must be taken to prevent the spread of the disease to family members and the community at large. Thus, the supervision and followup of home care patients will become an increasingly important activity for health departments. The need for establishing criteria for the selection of home care patients is also intensified, since in many cases it is the health department's legal responsibility to decide whether the patient must be hospitalized.

Directors of tuberculosis hospitals are eager to make sure that adequate followup is available for patients discharged under isoniazid therapy. In one State, a Veterans Administration hospital reimburses local health departments for periodic X-rays and sputum tests of patients who have been discharged under isoniazid therapy. The health departments provide followup services and thus are able to work with the families of these patients. This arrangement, in which the local health department serves as liaison between patient and hospital, has been approved by the local medical societies.

The Public Health Service is developing a similar program in Alaska. We have contracted with the Territorial health department to conduct an experimental tuberculosis case-finding and home care program as a part of the Alaskan Native Health Service for which we are now responsible.

We can no longer say that the development of home care programs is a future charge on health departments. The time is now. Not only has the entire pattern of tuberculosis control changed, as has syphilis control, the discharge of mental patients under treatment with new drugs is a present problem. The return of mental patients to the community is placing important responsibilities on health departments and mental health authorities not unlike the demands for followup and supervision in the extensive use of isoniazid.

Every State and Territory is now in a position to reduce rheumatic heart disease substantially as a cause of disabling illness and pre-

mature death, and at the same time reduce markedly the onset of rheumatic fever. Progress against these diseases can be added to the long list of public health accomplishments even with future improvements in available techniques.

The recommendations of the Committee on Prevention of Rheumatic Fever and Bacterial Endocarditis of the American Heart Association have the full endorsement of the Public Health Service and the Children's Bureau. We are cooperating actively in the promotion of antibiotic treatment of all cases of streptococcal infection and chemoprophylaxis of recurrent attacks of rheumatic fever.

Public and private agencies have made a good start. They are sponsoring rheumatic fever clinics in more than 600 communities. But if we are to call a halt to rheumatic fever and rheumatic heart disease, we must have thousands more cooperative projects. Through these clinics, practicing physicians, schools, and parents can obtain many necessary supporting services for rheumatic children. Psychiatric advice, educational and vocational counseling, social service, and public health nursing follow-up are made available. Consultative services for the physician in the diagnosis and management of rheumatic fever and rheumatic heart disease also are provided.

A direct attack on the mortality from cancer of the cervix and uterus can now be made. The very promising and challenging results of our demonstration of the cytologic test in large groups of women at Memphis, Tenn., and elsewhere are especially interesting from the point of view of public health administration, in terms of cost, personnel, time, and ease of performance.

Evaluation Studies

These and many other advances in medical and public health science make it essential that health agencies critically examine their present pattern of organization of community services. In marked contrast with public enthusiasm for every advance in the health sciences, public acceptance of the traditional public health structure—the local health unit—seems to have reached a passive state in many com-

munities. People are neither militantly for nor against it. No community institution can be in a more perilous condition than when it commands only passive acceptance.

It is time we found out the basic causes of this indifference. Fortunately, in recent years, there has been a stirring of interest in the evaluation of public health programs and services. The Kellogg Foundation has expressed an interest in the support of research projects in this area. The Public Health Service wants to assist the States and Territories in whatever ways seem feasible. Possible approaches include studies conducted by our own staff; assignment of personnel to assist in State evaluation studies; participation in cooperative projects; and research grants to independent investigators. None of these approaches is exclusive; we should like to know your wishes.

Evaluation studies will require different approaches from those commonly employed in the study of disease behavior or in the rating of community health on a predetermined scale. The intent is to study community patterns and the bases of "health behavior" both in professional health workers and in the public they serve. We shall need the help of sociologists and psychologists as well as that of epidemiologists and statisticians.

Wide Spectrum Problems

Although at the moment we do not know precisely what are and what will be the most effective methods of organizing health services, we certainly know that public health has outgrown the "four-man health unit." New responsibilities have broadened the outlook at the State level to include some of the most stimulating challenges that the health professions have ever encountered.

To borrow a word from this antibiotic era of medicine, we must now be concerned with "wide-spectrum" health problems. The wide spectrum of public health today includes attention to the health and medical components in the broad fields of vocational rehabilitation, welfare, education, employment security, agriculture, housing, water resources, and many others.

Leaders in these fields are constantly turning to public health agencies for advice and co-operation. We, too, must turn to them, offering at the same time our best efforts in the solution of mutual problems. If public health is to go from strength to strength, we must take our opportunities to apply the concepts of prevention in some of these wide-spectrum fields.

Our relationships with our colleagues must be more than routine. If our cooperation is not more than lip service, these agencies will hire their own physicians and health staffs and ignore us. In this challenging period of history, applied science is revolutionizing the material aspects of our universe. If the incredible advances in technology are to be applied with maximum benefit to human life, we must have the widest possible range of bold, creative thinking in the social sciences and in the organizations whose responsibilities are the application of health, educational, and sociological knowledge. We in public health cannot possibly imagine that we possess all the brains, all the wisdom, all the creativity. We need our colleagues in a score of fields, as they need us.

Also, we must redouble our efforts to indoctrinate our State and local medical societies in the values of wide-spectrum health services. We must realize that for nearly a century, general practitioners have had almost no experience in the management of mental and tuberculous patients, for example. Under State laws, this has been the responsibility of the State. Now, advances in medical science are returning many of these patients to the general practitioner, who is also treating an increasing number of aged and chronically ill patients in their homes. But medical care today includes many types of service: nursing, physical therapy, and social work and other related services also must be made available to the home care patient.

Medical societies can be a most constructive influence by encouraging their members to utilize community nursing and related services in the care of these patients. Many urban communities now offer home nursing care, physical rehabilitation, and housekeeper services through the combined programs of official and voluntary health agencies. In smaller communities and

rural areas, the opportunity for organizing home nursing services presents a direct challenge to local health departments.

Plans have been developed on the west coast to provide dental care for dependent children of the members of prepayment medical care plans sponsored by labor and management groups. This experiment is of signal importance, since there is a growing demand for prepayment dental care plans covering the general population.

The difficulties inherent in the development of actuarially sound dental health insurance have been widely discussed. The demonstrations conducted by the Public Health Service in cooperation with State and local health departments and dental societies have provided valuable cost data and methodological information on the provision of dental services for children. State health department staffs may find these studies useful should they have opportunities, with State dental societies, to assist in the development of similar programs in their areas.

The health component looms large in such many-faceted social problems as juvenile delinquency, drug addiction, alcoholism, and accident prevention. Society now recognizes that ill health—physical, mental, emotional—is a major factor in producing deviant behavior. Still more encouraging is the growing acceptance, by the groups directly concerned, of preventive medicine and public health as vital parts of the total therapy of these massive problems.

Courts, law enforcement agencies, churches, schools, industries, voluntary organizations, and other groups will turn more and more to their health agencies for help, if help is offered. We should be ready and willing to contribute our best thinking and to participate actively in national, State, and local programs dealing with human behavior that is just as destructive to the individual and the community as is the behavior of an uncontrolled epidemic disease.

Some health departments have begun to explore these areas, in order to identify specific factors and to determine the role they can best play. The team approach to home accidents that has been developed by several State and local health departments, in cooperation with the Public Health Service and the Kellogg

mature death, and at the same time reduce markedly the onset of rheumatic fever. Progress against these diseases can be added to the long list of public health accomplishments even with future improvements in available techniques.

The recommendations of the Committee on Prevention of Rheumatic Fever and Bacterial Endocarditis of the American Heart Association have the full endorsement of the Public Health Service and the Children's Bureau. We are cooperating actively in the promotion of antibiotic treatment of all cases of streptococcal infection and chemoprophylaxis of recurrent attacks of rheumatic fever.

Public and private agencies have made a good start. They are sponsoring rheumatic fever clinics in more than 600 communities. But if we are to call a halt to rheumatic fever and rheumatic heart disease, we must have thousands more cooperative projects. Through these clinics, practicing physicians, schools, and parents can obtain many necessary supporting services for rheumatic children. Psychiatric advice, educational and vocational counseling, social service, and public health nursing follow-up are made available. Consultative services for the physician in the diagnosis and management of rheumatic fever and rheumatic heart disease also are provided.

A direct attack on the mortality from cancer of the cervix and uterus can now be made. The very promising and challenging results of our demonstration of the cytologic test in large groups of women at Memphis, Tenn., and elsewhere are especially interesting from the point of view of public health administration, in terms of cost, personnel, time, and ease of performance.

Evaluation Studies

These and many other advances in medical and public health science make it essential that health agencies critically examine their present pattern of organization of community services. In marked contrast with public enthusiasm for every advance in the health sciences, public acceptance of the traditional public health structure—the local health unit—seems to have reached a passive state in many com-

munities. People are neither militantly for nor against it. No community institution can be in a more perilous condition than when it commands only passive acceptance.

It is time we found out the basic causes of this indifference. Fortunately, in recent years, there has been a stirring of interest in the evaluation of public health programs and services. The Kellogg Foundation has expressed an interest in the support of research projects in this area. The Public Health Service wants to assist the States and Territories in whatever ways seem feasible. Possible approaches include studies conducted by our own staff; assignment of personnel to assist in State evaluation studies; participation in cooperative projects; and research grants to independent investigators. None of these approaches is exclusive; we should like to know your wishes.

Evaluation studies will require different approaches from those commonly employed in the study of disease behavior or in the rating of community health on a predetermined scale. The intent is to study community patterns and the bases of "health behavior" both in professional health workers and in the public they serve. We shall need the help of sociologists and psychologists as well as that of epidemiologists and statisticians.

Wide Spectrum Problems

Although at the moment we do not know precisely what are and what will be the most effective methods of organizing health services, we certainly know that public health has outgrown the "four-man health unit." New responsibilities have broadened the outlook at the State level to include some of the most stimulating challenges that the health professions have ever encountered.

To borrow a word from this antibiotic era of medicine, we must now be concerned with "wide-spectrum" health problems. The wide spectrum of public health today includes attention to the health and medical components in the broad fields of vocational rehabilitation, welfare, education, employment security, agriculture, housing, water resources, and many others.

this perplexing problem: cooperative planning and provision of services for the care of long-term patients—regardless of the causes of disability.

A new concept is emerging of the kinds of services and facilities that will be required for comprehensive care of the chronically ill, the disabled, and the aged. This concept recognizes the need for a wide variety of services and facilities, but the emphasis is on prevention and rehabilitation. The patient is viewed as a person in his home in his own community where he will receive the greatest part of his care under the supervision of his personal physician. The community remains the central factor in any plan for his care.

Application of this concept presents our State and local health departments with many opportunities to work with practicing physicians for better health of the individual, the community, and therefore, of the entire Nation.

I have mentioned some areas for work, and I am sure that you can name many more. The question before you now is "How many health departments will seize the opportunities—and when?"

Current Trends In Child Health

3

By Martha M. Eliot, M.D., Sc.D.
Chief of the
Children's Bureau

For those of us in the Children's Bureau, this meeting is a high point in the year's activities. The very process of reviewing the highlights of the past year that are significant for mothers and children may suggest new activities or new ways of strengthening older programs.

The increase to \$15 million in the appropriation for the crippled children's program is evidence of the widespread interest in the handicapped child and of skillful administration of the crippled children's programs by the States.

In 32 States they have become significant community medical care programs in which the quality of service is recognized as exemplary.

To assist in the continued development of these programs, regional conferences of State crippled children's agencies have been held recently. Some of the Nation's outstanding specialists in orthopedics, epilepsy, psychiatry, congenital heart disease and rheumatic fever, hearing impairment, mental retardation, and cerebral palsy took part.

The increasing concern about long-term illness in childhood to some extent reflects changes that have been taking place in pediatric practice. With the specific agents available for treating acute infectious diseases, fewer children with such illnesses now need hospital care. Many can be treated at home or in outpatient clinics.

Consequently, chronic diseases and crippling conditions now make up a greater proportion of illnesses in childhood and account for a growing proportion of pediatric inpatients in hospitals. This increasing trend is beginning to make a reorientation necessary in the teaching of medical students and nurses and in the post-graduate work of physicians.

Helping Crippled Children

From our experience with the administration of the State crippled children's programs we have learned much about the importance of a multiprofessional approach to the patient—an approach which considers his individual personality and stage of growth, his handicap or illness, his family and the community in which he lives, and what kind of an adult he may become. Together we have learned much about the principles and policies underlying the administration of a medical care program.

The crippled children's program has been fortunate in having the devoted support of members of the medical and related health and social work professions. Indeed, these programs could not have continued if we had not learned how to work with medical professional organizations and with the many public and voluntary organizations whose cooperation and participation are so important.

Children suffering from congenital heart dis-

Foundation, offers a valuable method for future study of the health component in highway accidents. The home accident prevention demonstrations pay special attention to the physical and psychological factors, as well as the environmental factors.

Highway engineering, improvements in motor vehicle design and construction, strict law enforcement and education combined have not sufficed to cope with the national problem of motor vehicle accidents. Death rates from this cause have increased steadily for the past 3 years.

We have not learned why the human being behind the wheel, or in the path of a car, behaves as he does. Nor have we learned what to do about his behavior when it is antisocial or self-destructive. We suspect that certain factors may be the basic "causes" of accidents.

We do know that the quality of driving is the chief cause of nearly 40,000 deaths chalked up to "motor vehicle accidents" annually, as well as an estimated 1,300,000 nonfatal injuries. More than 1 million of these nonfatal injuries result in total temporary disability, and 100,000 in permanent impairments. These facts would seem to call for action on the part of local, State, and Federal health agencies as insistently as the spread of infectious diseases.

The Perennial Problem

The shortage of adequately trained public health workers remains critical. This is our perennial problem. Health officials are especially concerned because we are making little headway in reducing the backlog of inadequately trained public health workers. Actually, in some categories, the backlog is increasing. The numbers of sanitation and nursing personnel receiving 4 months or more of advanced training have dropped since 1947 by 68 and 62 percent, respectively.

Public health agencies at all levels must learn to utilize their highly trained personnel more effectively. Auxiliary workers can perform many functions efficiently without having the advanced training now believed necessary for many routine operations. These workers must be used much more extensively. A career in public health must be "sold" to more medical

students, nurses, and engineers. Pay scales must be made more realistic and attractive.

Despite the shortage of additional public health recruits with advanced training, health agencies, official and voluntary, should push ahead with the expansion and enrichment of their programs. This is one way to improve recruitment. No matter how many competent men and women are trained, health agencies that offer only routine jobs will always have difficulties in recruiting and especially in holding able young employees.

Our professional schools, including graduate schools of public health, are increasingly concerned with the challenges of wide-spectrum health services. They have the capacity to turn out students who want careers in organizations where they can use the new knowledge and skills they have acquired. Health agencies must make their jobs attractive to graduate students. Many times, a truly satisfying job in a challenging field will counterbalance the deterring effect of low pay.

We cannot expect young men who have received their first training in electronics, nuclear engineering, and industrial processes to be satisfied with routine sanitation operations. No more can we expect young physicians who have been indoctrinated with the new concepts of chronic disease control, medical rehabilitation, hospital administration, and mental hygiene to be satisfied with assignments only to routine immunization clinics and repetitive case finding in traditional control programs.

Further Observations

Even though there are far more jobs to be done than there are people to do them, or funds to pay for the doing, we must take heart and go forward. It is not possible for any one organization to do the whole job. We have not yet begun to utilize all the resources that our communities may have in reserve. The health agencies can often accomplish more by being the active sparkplug and generator than by attempting to be the entire engine.

We have learned this lesson after a few years of desultory effort to control a few chronic diseases. Now we are seeking new approaches to

Last year, the lunch program reached a peak of 11 million youngsters. A special milk program, launched for the first time, resulted in an increased consumption of 451 million half-pints of milk by well over 8 million children.

The Incidence of Prematurity

The decline in infant mortality has caused many people to look closer at the problem of perinatal mortality, that is, fetal and neonatal losses. In 1953, fatalities to infants before, during, and just after birth numbered about 162,000. These deaths were about 10 percent of the total mortality in the United States at all ages and from all causes. Much of this perinatal loss is associated with premature termination of pregnancy. About 57 percent of all neonatal deaths are in premature infants. When the small premature infant survives, chances of neurological disorders are greater than for the full-term baby whose mother's pregnancy has been free of complications.

To assist us in our efforts to reduce the incidence of prematurity, the Children's Bureau is working with the National Office of Vital Statistics, State health departments, and other groups to get more trustworthy statistics about the incidence of prematurity and the bearing of socioeconomic, familial, and clinical factors upon its occurrence.

To this end, we are working toward more complete and accurate reporting of fetal loss and for wider agreements among clinicians, public health statisticians, and directors of maternal and child health programs as to how we shall study significant events in the mother's pregnancy and in the prenatal period. We are also consulting with a number of States on their studies of prenatal mortality and prematurity.

Blindness in premature infants may soon be rare now that excessive oxygen administration has definitely been implicated in its causation. State health departments have publicized to the medical profession the conclusions drawn from the study of retrolental fibroplasia in 18 hospitals. Although the incidence of this pathological condition has dropped in numerous hospitals, more work is needed to assure a higher

degree of accuracy in the concentration of oxygen being supplied to infants in incubators. The limitation in the use of oxygen when necessary for very small infants does not seem to have resulted in a higher mortality among premature infants as was feared.

Poison Control Centers

With accidents the leading cause of death among children, poison control centers are a new development in many cities. A committee of the Illinois Academy of Pediatrics cooperating with the Chicago Board of Health established the first center in 1954. There are centers in Boston, Cincinnati, Dallas, Durham, N. C., Indianapolis, Louisville, New York City, Phoenix, Springfield, Ill., and Washington, D. C. Poison control centers provide information on toxic household chemicals, advise hospitals on appropriate treatment, and educate parents on prevention and first aid.

Mental Retardation

Last year I reported that parents of mentally retarded children were doing much to bring to public attention the problems they have in bringing up their handicapped children. The Children's Bureau is currently making grants to three States for special projects in this area. Other States are developing plans for diagnostic evaluation centers and for day-care centers, nursery school classes, social services, and other community resources. The Congress has expressed considerable interest in this problem and has encouraged the Department of Health, Education, and Welfare to extend its activities in this field.

Mental retardation was the subject of a discussion this year by the Federal Interdepartmental Committee on Children and Youth. Reports were presented on the current activities of the National Institute of Mental Health of the Public Health Service, Office of Vocational Rehabilitation, Bureau of Employment Security, Office of Education, and the Children's Bureau. The committee is planning a 2-day seminar on mental retardation for the spring of 1956.

ease are now being treated with a success that was only dreamed of a decade ago. Today's operative techniques not only save the lives of many of these babies but give them a chance to grow up normally.

At the Second World Congress of Cardiology (1954), two-thirds of 244 children helped by the Blalock-Taussig operation were reported to be maintaining their gains 5 to 8 years later. The improved operative procedure makes it possible to repair defects inside the hearts of babies less than a year old and of older children as well.

Among the newest of the special projects under the crippled children's program are those in California and Michigan for the development and use of artificial hands. The grant to Michigan is enabling the Crippled Children's Commission to serve as a regional resource, extending help to many children in the mid-west. This program, like the one for children with congenital heart disease, is another example of how the benefits of research, especially those of such highly technical and costly types as these, can be made available to children in rural areas through organized programs administered by public agencies.

School Health Services

Two significant conferences on school health were held in October 1955: the Fifth Annual National Conference on Physicians and Schools and the National Conference on Priorities for Nursing Services for School Age Children. The health of school age children will be featured at the November 1955 meeting of the American Public Health Association in Kansas City.

The Children's Bureau works closely with the Public Health Service on many undertakings aimed at improving the health of mothers and children. The Bureau, the Public Health Service, and the Office of Education, through the Departmental Committee on School Health, review ways in which we can be of assistance to State health officers.

This heightened interest in school health services, as in education itself, is largely a result of pressures brought about by the increase in the child population.

The United States has 37,277,000 children of school age, children between 5 and 17 years of age. All need basic health care, including comprehensive medical and dental examinations at periodic intervals with special consultation and diagnostic service as required; immunizations against contagious diseases; continuous observation by parents, teachers, nurses, and others to detect early deviations from the child's usual physical, nutritional, or emotional well-being; frequent tests of hearing and vision; and the correction and treatment of physical and mental defects and conditions, particularly those likely to interfere with educational progress and normal growth and development.

Case finding of physical handicaps has value only to the degree that parents obtain the necessary medical attention for their children. That many children do not receive corrective follow-up before adulthood is attested by the rejection for medical reasons of 46 percent of selective service registrants between 1948 and 1955.

Studies have repeatedly brought out that children do not receive the treatment recommended by school health services because of the parents' inability to pay for care, the lack of appreciation on the part of parents and children of the importance of taking the necessary steps to obtain care, and the inadequacy of resources to provide diagnosis and treatment, particularly of a specialized nature, in rural areas and in the new suburbs and communities that spring up near rapidly expanding industries.

School Lunch Program

The National School Lunch Program continues to improve the health of vast numbers of children. We are well aware that the nutritionists in the State health departments, the maternal and child health divisions, have made real contributions to this program.

The 1955-56 program, enriched by grants and surplus foods from the United States Department of Agriculture, is expected to exceed \$600 million in money value, half of which will come from the children who consume the low-cost meals and milk and close to a third, from the Federal Government.

the importance of understanding the factors influencing personality development.

The conference discussed school health services as a resource for the prevention of delinquency and emphasized these points:

- Early identification of high risk children.
- Spotting symptoms of aggressive or withdrawn behavior (stealing, truancy, not working to capacity, reading retardation).
- The need for child guidance services in the health programs in schools.
- The use of ancillary personnel without formal training for counseling.
- The need for more emphasis on the emotional component of growth and development in the training of all professional persons.
- Ways in which personnel can help prevent situations of crisis proportions and provide first aid when a crisis arises.
- Responsibility of health personnel for taking action.

A symposium on juvenile delinquency was a prominent feature of the recent annual meeting of the American Academy of Pediatrics.

The symposium was directed particularly to the health aspects of the subject, to the role of the practicing pediatrician in prevention and treatment, to the importance early relationships in the family have for personality development. Frequently, the social and moral environment makes it difficult for children to establish satisfactory relationships between themselves and the world in which they live.

In closing, I would like to return to the matter of the responsibility of the State health departments for maternal and child health and crippled children's services. These two programs, when in one State agency or when closely coordinated in separate State agencies, contain all the elements necessary to provide adequate health care for children. It seems to me that possibly these services and facilities could be used more effectively to the great advantage of many children known to other State agencies, particularly agencies providing for welfare and education.

Earlier, when I referred to the current interest in school health services, I did not speak specifically of the children for whom the child welfare programs are responsible—the children

in institutions, in foster family care, or in their own homes—or of the large group of dependent children who are deprived of parental support and in receipt of public assistance, or of children dependent on local relief. No doubt various lines of cooperation exist in many States and communities. I bring this question to your attention now so that you and your staffs may perhaps renew your consideration of whether the best use is being made of your resources.

Community Air Pollution, A Developing Health Problem

4

By Justin M. Andrews, Sc.D., LL.D.
Associate Chief for Program,
Bureau of State Services,
Public Health Service

Until recent years community air pollution in the United States has been regarded as the cause of a series of local problems susceptible to local solution. However, the expansion of population and industry in the past few decades has combined hundreds of air pollution sources into composite air pollution areas with which individual local authorities cannot cope on the basis of present knowledge. These areas have developed air pollution problems of enormous complexity involving more than one State in some cases and, in many instances, a large number of uncoordinated legal jurisdictions.

The simultaneous outpouring of many gases, fumes, and particulates into the Nation's ambient atmosphere, and the subsequent interactions and combinations of these pollutants in the air have damaged vegetation, livestock, physical structures and other materials, and have decreased property values. Among exposed populations, it has caused untimely deaths, unnecessary suffering, acute and prolonged irritation.

If permitted to continue without restriction, community air pollution may be expected to

Migratory Workers

Following the East Coast Migrant Conference last year all of the 10 States in the east coast migrant stream have been active in different ways.

Pennsylvania is developing day-care centers in Potter County.

Florida is completing the first stage of a special study of the health problems of migrant families as recognized by the migrants themselves. The study will provide basic information which should be useful in making realistic plans to extend help to children and their families.

Colorado and Idaho have special health projects for caring for migrant families.

Some of the State health departments are using maternal and child health and crippled children's funds or State funds to increase health services in areas to which migrants come. States have been ingenious in finding ways of overcoming the staffing problem at peak seasons, for example, by employing medical students in the summer, high school science teachers as extra sanitary inspectors, and by assigning school nurses to assist the regular public health nurses in the summer term.

The President's Committee on Migratory Labor has completed its first year of coordinated Federal activity. In October 1955 this Cabinet-level committee laid out a program for the coming months. Among its activities it will seek ways of easing residency requirements for eligibility for service—requirements which disqualify migrants in many programs, especially welfare and medical care. Another activity will be studies of housing needs.

Protecting Adoptions

Problems of unmarried mothers and the adoption of children have long been a major interest of the Bureau. The most publicized problem is that of the number of children being adopted without minimum protections, the babies who are sold to adoptive couples. The idea of selling babies is intolerable, but the practice continues.

The Children's Bureau has sought the knowledge of people who have had contact with one or more of the parties to a black market adop-

tion. The line between a black market placement for money and many others where money does not change hands is very fine indeed. The hazards can be just as great for the child, his natural, and his adoptive parents.

We have asked some preliminary questions regarding the availability and adequacy of medical care for unmarried mothers, about legal requirements and restrictions on community services to girls who have left their home to lose themselves in a big city, about the availability and adequacy of social services, about certain policies and practices of adoption agencies that seem to facilitate or hinder the meeting of the needs of the unmarried mother and her child, about agency practices regarding the couples who want to adopt children.

In June 1955 the Bureau held a conference with 31 national agencies and organizations to discuss the need for protecting children in adoptions. The Academy of Pediatrics, the Academy of General Practice, the American Hospital Association, the American Public Health Association, the Academy of Obstetrics and Gynecology, the Association of State and Territorial Health Officers, and legal and social agencies were represented.

The conference brought out the need to concentrate on providing medical and social services acceptable to the unmarried mother, clarifying the responsibilities of the professions concerned in adoptions, and securing legislation which will assure legal safeguards to protect the child, his natural and adoptive parents.

The Bureau employs a special consultant on unprotected adoptions and services to unmarried mothers.

A study of the problems involved in providing medical care to these mothers is being contemplated.

Juvenile Delinquency

In May 1955 the Children's Bureau called a conference on health services and juvenile delinquency in which State health department personnel participated. It was one of the few occasions when a conference on delinquency has focused on the relationship of delinquency and child health and public health. The discussion centered on the parent-child relationship and

the general philosophy of the ad hoc committee, as indicated above.

Air Pollution Control Act

On July 14, 1955, the President approved Public Law 159, following its passage by the Congress. The Air Pollution Control Act authorizes the Surgeon General of the Public Health Service, under the supervision and direction of the Secretary of Health, Education, and Welfare, to conduct a program of research and technical assistance relating to air pollution, with an appropriation not to exceed \$5 million annually for each of the fiscal years 1956 through 1960.

The act declares "the policy of Congress to preserve and protect the primary responsibilities and rights of States and local governments in controlling air pollution, to support and aid technical research, to devise and develop methods of abating such pollution, and to provide Federal technical services and financial aid to State and local government air pollution control agencies and other public or private agencies and institutions in the formulation and execution of their air pollution abatement research programs."

This is a very broad act which recognizes that air pollution may endanger health and welfare, injure agricultural crops and livestock, damage property, and create hazards to air and ground transportation. Thus, it is not limited to health in its implementing provisions.

Specifically, the Surgeon General is authorized or enjoined, with respect to air pollution and its control, to—

Cooperate with governmental (Federal, State, and local) and private agencies, institutions, industry, and other organizations in preparing research programs and in undertaking joint studies with any such groups.

Encourage cooperative activities by State and local governmental agencies.

Collect and disseminate information.

Conduct research in the Public Health Service and support and aid the conduct of research by State and local air pollution control agencies and other agencies and institutions, and to publish the results thereof.

Conduct investigations and make surveys

concerning specific problems when requested by any State or local air pollution control agency, and publish reports of findings.

Make grants or let contracts for research, training, and demonstration projects to State and local government air pollution control agencies, and other public and private agencies and institutions, and to individuals.

A supplemental appropriation to implement Public Law 159 was passed also at the last session of Congress. This appropriation plus funds from the Public Health Service regular appropriation makes a total of \$1,785,000 available for community air pollution research and technical assistance during fiscal 1956.

Program Under Way

The technical assistance program has been initiated. Personnel have been assigned to assist the Los Angeles Air Pollution Control District through the California State Department of Public Health. Similar assistance has also been extended to Louisville, Ky.

Requests for extensive investigations have been received from 28 State governments and local communities as of November 1, 1955. These requests do not include the numerous calls for consulting services received from many other different parts of the country.

Short courses in the technical aspects of air pollution control are scheduled to be held at the Robert A. Taft Sanitary Engineering Center of the Public Health Service in Cincinnati. No funds for training or demonstration grants are available during fiscal 1956.

The research activities planned for this fiscal year will be carried on (a) directly by the Public Health Service in Cincinnati both at the Sanitary Engineering Center and at the Occupational Health Field Headquarters, (b) by other agencies of the Federal Government, and (c) by Public Health Service grantees and contractors.

At the Sanitary Engineering Center, the nationwide, aerometric survey begun approximately 2 years ago will be expanded. Preliminary estimates of classes and determinations of amounts of particulate loadings have been obtained from air samples collected on daily and weekly schedules in more than 30 representative

cause increasing hazards wherever it occurs. Such harrowing episodes as those which took place in Glasgow in 1909 and 1925, the Meuse Valley of Belgium in 1930, London in 1948 and again in 1952, Donora, Pa., in 1948, and in Poza Rica, Mexico, in 1950, signify what may occur in many other places, unless means can be found to contend effectively and economically with aerial effluents which threaten life and property.

Ad Hoc Committee

Public and official attention was again directed to this menace during recent years by the disturbing occurrences of community air pollution, or "smog" as it is locally known, in the Los Angeles area. The Congress was concerned not only about the California situation but about the evidence of increasing atmospheric pollution in other States.

At the informal suggestion of the White House, the Secretary of the Department of Health, Education, and Welfare invited the heads of certain other Federal agencies and departments—Atomic Energy Commission, Agriculture, Commerce, Defense, Interior, and the National Science Foundation—to nominate policy level representatives to an Ad Hoc Interdepartmental Committee on Community Air Pollution.

The first meeting of this group convened under the chairmanship of the Surgeon General of the Public Health Service on November 16, 1954. Several other conferences were held thereafter, some of them with technical deputies from the various agencies.

For its own purposes, the committee developed the following definition of community pollution:

"Community air pollution is the presence in the ambient atmosphere of substances put there by the activities of man in concentrations sufficient to interfere directly or indirectly with his comfort, safety, or health, or with the full use and enjoyment of his property. In general, it does not refer to the atmospheric pollution incident to employment in areas where workers are employed, nor it is concerned with airborne agents of communicable disease, nor with overt or covert acts of war."

The committee reviewed the statutory bases for the interest of the participating agencies and appraised existing knowledge pertaining to community air pollution. Members were unanimous in the conviction that existing gaps in essential information could be filled only by coordinated research specifically directed to the problem by competent medical, scientist, and engineer investigators. They expressed the belief that the determination of basic criteria of air cleanliness in the community atmosphere is a public responsibility and that such criteria must be based on definitive, scientific data and considered in relation to all the pollutants present.

The committee recognized that the funding of comprehensive studies as a basis for these determinations and for the establishment of facts concerning nonindustrial community air pollution was beyond the usual resources of single States. In view of the national interest, therefore, the committee considered that it was a proper responsibility of the Federal Government to provide leadership and supplementary means in solving these and related air pollution problems, making the most effective utilization of existing competencies and facilities, and inviting and encouraging as much research as can be performed or supported by States, industry, and other agencies.

As to the role of Federal and State-local governmental agencies in controlling and regulating community air pollution, the committee recommended the designation of the Department of Health, Education, and Welfare to sponsor and support pertinent legislation and to direct a Federal program in this field; and the establishment of an interdepartmental committee on community air pollution on a continuing basis. The committee also suggested the scientific areas in which funds should be assigned if appropriated by Congress. This information is contained in a report released on April 8, 1955.

In the meantime, several bills, amendments, and joint resolutions pertaining to air pollution had been proposed in Congress. In reporting on them to the congressional committees concerned, the Secretary of Health, Education, and Welfare made suggestions consistent with

of contract research to provide information concerning the health effects of subacute exposures to pollutants suspected to be harmful. This is probably the most important single fact to ascertain. Thus far, it has been the most elusive since most air pollution control ordinances are written on the assumption that freedom from community air pollution will be healthful.

It is hoped that organ function tests, especially pulmonary and cardiovascular, can be devised for use on a mass basis. Such tests might be applied, according to conventional epidemiological patterns, to population groups comparable in all important respects except for their exposure to high or low levels of specific air pollution.

Similarly, chest X-ray surveys may be made along epidemiological lines to see whether lung cancer is more prevalent in populations exposed to continued, high levels of air pollution.

Efforts are also planned to determine whether tissue culture techniques offer a more sensitive indication of the toxicity of air pollutants than do intact test animals.

Contract research will be employed by the engineers for the development and construction of special equipment such as automatic, recording air analyzers capable of measuring several air pollutants simultaneously.

These are the tentative directions in which the air pollution program is now headed. As new facts become available, more of the research will probably shift from emphasis on causes and effects to ways and means of preventing or controlling community air pollution. In time, more of the funds may be used for demonstrations and training than for research.

In view of the complexities of the problems involved and the frustrating experiences in control efforts thus far, it seems unlikely that immediate or short-time results can be expected. The ad hoc committee was of the opinion that at least 2 years would be necessary to build up to the desirable level of research activity, and that 5 years of intensified effort at the maximum budgetary level specified by Public Law 159 would be required to produce research findings of major significance.

Research Factors In the Control Of Uterine Cancer

5

By Raymond F. Kaiser, M.D.
Chief, Field Investigations and
Demonstrations Branch,
National Cancer Institute

Since cancer presents no symptoms in the early stages, the development of a case-finding method for discovering uterine cancer in a really early stage of the disease represented a difficult research undertaking.

Thanks chiefly to the research efforts of Dr. George N. Papanicolaou, we have such a procedure today. This is the cytologic technique for examination of exfoliated cells in vaginal smears. The technique is based on the fact that since cancer cells do not adhere closely together, and consequently shed readily, with proper staining they can be distinguished microscopically in smears of vaginal secretions.

Papanicolaou Test

The Papanicolaou technique has been a long time coming to its present acceptance for a number of reasons.

The idea of studying the exfoliated cells in various secretions of the body is not new. Examination of the vaginal fluid was first performed by Pouchet more than 100 years ago. His interest, however, and that of many investigators who followed him, was related to analysis of the normal human sex cycle and to the problems of sex physiology.

Papanicolaou was also doing research in the field of sex physiology when in 1923 he first applied cytology to the diagnosis of uterine cancer. His new discovery was duly reported in the literature, but, despite this early recognition of the possibility of diagnosing uterine cancer by this means, the interest of clinicians in the potentialities of this diagnostic method was not aroused.

communities. These include both urban and rural areas. Inorganic assays and quantitative analyses of certain organic constituents are made of the present particulate collections, and it is planned to supplement these by routine determinations of some of the nonparticulate pollutants (gases and fumes) in the near future.

At the Occupational Health Field Headquarters, work is already under way in determining the physiological and toxicological effects of certain chemicals, such as ozone, oxides of nitrogen and sulfur, and complex hydrocarbons known to be present in smog.

Certain research problems in air pollution can be studied more advantageously and economically by other Federal Government agencies in addition to their regular activities because of staff competencies and special facilities which they possess. Thus, arrangements have been made to transfer funds for special projects to three such agencies.

The United States Weather Bureau will make basic studies of the meteorological factors governing diffusion and dispersion of pollutants in the atmosphere and develop techniques of forecasting critical meteorological conditions in relation to air pollution.

The National Bureau of Standards will develop methods for sampling and analysis of certain air pollutants about which little is known and study their chemical and physical nature and the reactions at sources and in the atmosphere which may combine, split, or otherwise modify them, creating different and perhaps more or less harmful compounds.

The Bureau of Mines, Department of the Interior, will investigate methods of incineration of combustible wastes, evaluate sulfur dioxide removal processes, determine the composition of and changes in automobile exhaust effluents, and participate in special community investigations.

Arrangements also are being made for the Veterans Administration to undertake statistical studies of their physical examinations, case histories, morbidity and mortality experience among veterans who are known to have had long residence under conditions of relatively high or low exposure to known types of air pollutants. This effort to obtain sugges-

tive clues from retrospective data concerning impairments which may ensue from chronic, accumulative exposures would require many years of watchful waiting to detect by the methods of prospective epidemiology.

A similar study, on a contract basis, is planned with the Society of Actuaries with reference to medically impaired insurance policyholders.

Grants-in-Aid

All grants-in-aid authorized by the act are for research, training, or demonstration projects. There are no formula-type grants for general program support. Only research grants will be made during this fiscal year.

Of the \$500,000 available for research grants in 1956, approximately \$300,000 already has been committed for support of air pollution studies. Most of the research grants awarded so far have been for studies primarily related to the health effects of air pollutants. Investigations under way include broad epidemiological studies of the relation of human disease to air pollution, studies of the effects of specific contaminants such as fluorides and oxides of sulfur, and studies of physiological response to air pollutants.

It is expected that future research grant projects will include studies on the causes and prevention of air pollution as well as those concerned with its effects on health.

The Division of Research Grants, National Institutes of Health, administers the processing of research grants. The air pollution research grants program is somewhat different from similar programs of the Service. It is authorized by separate legislation which is not limited to health considerations, although these are of a high priority, but is sufficiently broad to cover any research related to the causes, effects, or control of community air pollution. Adequate liaison will be maintained with Federal agencies to avoid duplication with other grant or research programs relating to air pollution.

Contract Research Plans

The medical component of the community air pollution program is planning an extensive use

Of the cancer found, intraepithelial cancer occurs in younger age groups with a peak of incidence about age 33. The peak incidence of the invasive cancer is at age 52. This suggests that cancer of the cervix may exist for varying periods of time in a noninvasive form when it is completely curable.

Mass Screening Potential

Experience indicates that the vaginal smear technique is an excellent procedure for finding cases of cancer. It will effectively screen out from the general population suspicious cases needing further study by biopsy, but a positive report on cytology examination is not a final diagnosis and biopsy examination must confirm the smear report before definitive therapy is carried out.

The many questions which remain concerning the control of uterine cancer can be answered only through additional investigations and research.

Research with the cytologic technique may answer questions that bear directly on the problem of controlling uterine cancer, questions such as:

- Does the carcinoma in situ lesion progress invariably to invasiveness?
- What is the true incidence and prevalence of the lesion?
- What is the earliest age at which the lesion occurs?
- Are there even earlier stages of the lesion?
- How many of these lesions regress spontaneously?
- What is the duration of the lesion before invasion?
- What is effective treatment for the lesion?
- Can improvement be made in the method of screening the smears?

Some of the research is already under way. One study relates to the development of an electronic device to mechanically sort out the large mass of negative smears from the positive and suspicious. Such a machine within the foreseeable future should greatly reduce the number of trained technicians required for a screening survey.

Answers to some of the other questions will be sought in 5 or 6 other pilot studies which we

expect to establish throughout the country, principally in connection with medical centers.

Meanwhile our experience has led us to conclude that vaginal aspiration and cytologic examination of the smear are practical procedures for discovering cervical cancer on a mass basis. The widespread application of this technique could potentially reduce cervical cancer mortality.

Public Health Aspects Of Atomic Energy In Peacetime

6 By Daniel Bergsma, M.D., M.P.H.
New Jersey State Commissioner of
Health and Vice President, Association
of State and Territorial Health Officers

The emergence of the peacetime applications of nuclear energy is one of the beneficial concomitants of the development of nuclear weapons. Ionizing radiations are thus one more complexity that man has added to his environment. The consequent public health responsibility is to maintain all radiation exposure within the generally accepted limits without unnecessary interference with maximum utilization of radiation sources. Since its beginning in the early 1940's, the atomic energy industry has had a tremendous growth—first under the Manhattan Engineering District and then under its successor, the Atomic Energy Commission. The commission has capital assets of some \$12 to \$14 billion and an operating budget of almost \$2 billion a year. Private firms manufacturing equipment and devices needed in atomic energy work have investments and yearly sales running into many millions of dollars.

The amounts of radioactive materials dealt with have also increased enormously. A medium-size nuclear reactor, for example, may contain in the order of 100 million curies of radioactive materials. It is necessary to process

Possibly the fact that Papanicolaou was not a clinician but an anatomist working in a research field may have had some bearing on this lack of interest.

As a result of Papanicolaou's association in 1939 with Dr. Herbert F. Traut, and later with Dr. Andrew A. Marchetti, further investigations placed the use of vaginal smears in cancer diagnosis on a more solid basis. Papanicolaou and Marchetti introduced the endocervical and endometrial smear technique.

Following the close of World War II, reports by others began to appear in the literature recounting the use of this technique. Skepticism and doubt were expressed, particularly by pathologists, as to whether the technique could identify cancer cells. A portion of this resistance stemmed from the fact that by training and experience pathologists had learned to identify cancer on the basis of a section of tissue with a characteristic cell structure.

The numerous evaluations made of the accuracy and validity of the technique and the passage of time led to a change in the concepts of pathologists and an increasing acceptance of the technique as a diagnostic aid or screening technique for cancer.

Many clinical investigations have demonstrated that the Papanicolaou technique can indicate the probable existence of uterine cancer, particularly where the cervix is involved, even in the absence of significant signs or symptoms and without suggestive clinical evidence of the disease or gross findings.

Herein lies the greatest merit of the test. It permits the early recognition of incipient lesions such as carcinoma in situ, a microscopic lesion which is noninvasive and therefore 100 percent curable.

Here again there was reluctance to accept the findings, this time by the clinician. His resistance was based on the fact that for years uterine bleeding or spotting has been considered the cardinal sign of early cervical cancer. We now know that this is a sign of invasive cancer with ulceration rather than early carcinoma. Of necessity many studies and investigations had to be carried out to establish this fact.

As a consequence, the clinician's concept of early cervical cancer has gradually changed. In fact, at present it is believed that an appreciable

number of cervical cancers pass through the carcinoma in situ stage before invasion begins.

The Memphis Study

The technique still faced the criticism that there would not be enough professional people to carry out the procedure. This situation led to the establishment in 1951 of a study in Memphis and Shelby County, Tenn., by the National Cancer Institute in cooperation with the University of Tennessee Medical School divisions of pathology and bacteriology and of obstetrics and gynecology, the Memphis and Shelby County Health Department, the Shelby County Medical Society, the Bluff City Medical Society, and the Shelby County unit of the American Cancer Society.

The purposes of the study were to determine the feasibility and practicality of vaginal cytology as a general population screening procedure; to determine age-specific incidence and prevalence rates for preinvasive and invasive cancer; and to determine the course and fate of carcinoma in situ.

Initially in this operation, nonprofessional persons, under the direction of a nurse, obtained the smears from clinic patients; a staff of cytology technicians screened the smears, sorting out the suspicious and positive smears from the negatives; pathologists made the final interpretation of the smears and carried out the tissue examination of biopsies resulting from the suspicious and positive smears.

Early in the program most of the smears came through clinics conducted throughout the area. With acceptance, an increasing number of smears came from private practitioners, and now more than half of the smears reviewed are from that source.

The results have been encouraging. The cytology findings of the first 70,000 women screened were suspicious or positive in 1,327 women or 1.9 percent. In this group 282 intraepithelial or carcinoma in situ cancers and 245 early invasive cancers were found. From the point of view of cancer control, it is especially significant that 88 percent of the intraepithelial and 29 percent of the invasive cancers were not suspected either by the physician or the patient.

in advance of the time the reactor begins operation so that the data will be representative of seasonal weather conditions, and it should be continued long enough after reactor startup to enable the selection of sampling locations that will provide the most useful data. Subsequent samples from these locations will give a good indication of whether or not the installation is contributing any increase of activity to the naturally existent levels.

Such sampling will normally be conducted by the operators of the installation. However, for its own knowledge the responsible State agency should conduct spot checks of its own.

Disposal Problems

Under conditions of ultimate disposal, the wastes are far larger in volume, and activity levels are tremendously higher. These wastes will probably be due almost entirely to the chemical processing of reactor fuel elements. They may contain activity concentrations of several hundred curies per gallon. A further complication is introduced by the fact that a heat release of 2 or 3 British thermal units per hour per gallon of waste occurs as a result of the heat generated by the intense radiation. The higher the concentration of radioactivity, the higher the rate of heat release per unit volume and the greater the associated handling problems. Tanks containing highly concentrated wastes must be cooled to keep the liquid from boiling. Cooling of wastes adds substantially to the water demands of the installation.

Treatments which are effective in reducing or eliminating the toxic qualities of chemical wastes have no value whatsoever in dealing with radioactive wastes. The only method of disposing of radioactive wastes is by physical transfer from locations where they may be hazardous to areas where they will present no great threat. There is no chemical, physical, or biological means by which these materials can be made inactive or by which the rate of decay can be hastened. They can be made easier to handle by such methods as concentrating liquid volumes by evaporation or by making shipments in a number of small volumes to reduce shielding bulk.

At present, disposal of low-level wastes is by dilution to a safe level. This is obviously impractical with high-level wastes, since they would require dilutions of the order of 1 million gallons or more for each gallon of radioactive waste.

Several alternative solutions for high-level wastes have been suggested. Among these are pumping the wastes into permeable subsurface soils or into deep salt-bed formations. The theory behind these proposals is that the movement of ground water through such formations is so slow that a very large reduction in the amount of radioactivity would take place through natural decay before the activity could enter sources of potable water. Unfortunately, suitable geological formations are not located beneath the most convenient sites for processing plants.

Another proposal is to dump wastes in the oceans. The wastes would either be placed in suitable containers and allowed to sink to the bottom in about 1,000 fathoms of water, or they would be pumped to the bottom as liquids. Unfortunately, on the east coast of the United States the continental shelf extends many miles to sea, and our knowledge of deep ocean currents at present is not sufficient to enable accurate predictions of what the resultant dilution would be.

Because of the uncertainties involved in these proposed methods, the present solution is to store the wastes for years in underground tanks. In spite of precautions, it is always possible that such tanks may develop leaks and contaminate water supplies. Underground burial of solid wastes presents the same potential hazard. The problem of safe disposal of these wastes may well prove to be the limiting factor in the construction and operation of power reactors. If such wastes become free in the ground, they are beyond control. This problem may be one of the most critical facing us in public health.

A great deal of what has just been said relates specifically to nuclear reactors. A second large sphere of public health concern must be installations which are using radioisotopes for research and industrial purposes. Radioisotopes are presently available, not only from nuclear reactors, but also from particle accelerators.

chemically the fuel elements containing these vast quantities of radioactivity on a routine basis. In spite of this fact, the atomic energy industry has had a lost-time injury rate lower than any other major industry except communications. With the exception of a few accidents in connection with experimental work and the weapons testing program, no radiation injuries are known to have occurred.

Much of the Atomic Energy Commission's success in this respect is undoubtedly due to the enforcement of very conservative permissible exposure standards. The establishment of rigid control procedures at the inception of the atomic energy industry represents one of the few instances in which a major industry has set up a large program in health protection without the compulsion of a record of serious accidents.

Two Types of Hazards

The field of atomic energy presents two types of health hazards due to ionizing radiations.

The radioactive material may become airborne or may contaminate food or water and so may enter the body via the lungs or by ingestion. In this case, such factors as the metabolism of the element concerned, its physical and biological half-lives, and the type of radiation it emits must be taken into account in determining permissible body burdens. An element that tends to concentrate in a particular organ, as does iodine in the thyroid, will produce a different pattern of injury from an element that is non-specific, such as carbon or sodium.

The gamma rays and the beta rays of radioactive material constitute an external radiation hazard. Beta rays are high-speed electrons which can cause a burn similar to a thermal burn in the skin but which do not affect the deeper layers of tissue. Gamma rays are identical with X-rays in their action but have somewhat higher energies than the common diagnostic X-ray. They are highly penetrating radiations and tend to expose the entire body, or major parts of it, more or less uniformly. The radiosensitivity of tissues and the relative efficiency of various radiations in causing biological damage must be considered in setting permissible exposure limits.

Public health problems can arise under conditions of use of radioactive materials and under conditions of their ultimate disposal. In the first instance, exposure may result from external sources of radiation or from ingested or inhaled contaminants. Depending on the method of disposal, this may also be true of the second instance. However, a significant difference exists in that under conditions of use the material is presumably under the control of the user, whereas under conditions of ultimate disposal the material has passed beyond, or is only partially under, the user's control.

Problems of Use

One of the chief ways in which a public health problem may arise under conditions of use is the accidental release to the atmosphere or to the local liquid disposal system of radioactive materials. The release of radioactive material into the air or the disposal system is allowable provided the amount does not exceed permissible limits established by the Atomic Energy Commission. Small quantities are generally disposed of by sufficient dilution to keep resultant radiation levels below permissible limits. However, there is always the chance that malfunctioning of equipment or error on the part of personnel will allow the release of much larger quantities. In an effort to avoid this possibility, monitoring devices are commonly used in the effluent stream.

There is also the possibility of malfunctioning of the monitoring devices, and, in any event, the actual amount of dilution taking place remains a question. Therefore, it is necessary to measure radioactivity levels of air and water in downwind or downstream locations.

Since there may be appreciable variation in background, or natural, radioactivity from area to area, it is desirable that information on these levels be collected for various sections of a State. Where there is a major atomic energy installation, such as a nuclear reactor, it is sound practice to make a rather extensive investigation of the natural activity in the surrounding region, including soil and vegetation as well as air and water. The collection of data on background radiation should be started well

The Current Status Of Hospital Survey And Construction Programs

7

By John W. Cronin, M.D.
Chief, Division of Hospital
and Medical Facilities,
Public Health Service

Substantial progress has been made since the Hospital Survey and Construction Program was authorized in 1946. At that time the national bed deficit was in excess of 900,000. We now have 260,000 more acceptable hospital beds: 88,000 were constructed and put in operation through the Hospital Survey and Construction (Hill-Burton) Program.

The net gain since 1946 is much less than the total volume. In fact, it is only 70,000 beds, or less than 8 percent of the present estimated needs. This is influenced by the mounting obsolescence—physical and functional—and annual population increase. We have 73 percent of the general beds but only 56 percent of mental beds and 14 percent of chronic beds needed.

About one-third of all present hospital construction is through the Hill-Burton program. There are regional differences in volume of construction, which varies according to the average income of the area. Hill-Burton projects account for nearly all the construction undertaken in the lowest income areas but constitute only one-fifth of that in the wealthiest areas. This follows the basic intent to provide maximum aid to low-income States.

Some of the specific gains from the program include 2,600 approved projects which will provide 121,000 beds, and 1,900 completed projects which have provided 88,000 beds. In addition, 550 health centers, many related health facilities, and State health laboratories have been aided in their construction phases.

Progress in acquiring facilities in local areas may be measured by comparing 1946 figures, showing that 10 million people in 600 general

hospital service areas did not have access to acceptable hospital beds, with the current figures of 175 areas and 3 million people. However, there remain 336 other hospital service areas in which less than 50 percent of the total bed need has been met for a population of 23 million.

Specific illustration can be cited. In Alabama, the number of counties without acceptable general hospital beds has been reduced from 33 to 2, although 25 counties still have less than 50 percent of the need met.

Other benefits from the Hill-Burton program include assistance to teaching hospitals approved for intern and residency training, new teaching hospital facilities at university medical centers, improved design of hospital and related health facilities, new and better hospital licensure laws, minimum standards of hospital operation and maintenance established in all States, increased attention to related health facilities, and the development of an orderly system of planning for and providing hospitals and related facilities.

Six hundred communities now have hospitals where none existed previously. The nearly 800 new hospitals built in towns of less than 5,000 may serve well as evacuation destinations for critical areas in times of national catastrophe.

The 1954 Amendments

The Medical Facilities Survey and Construction Act of 1954, amending the Hospital Survey and Construction Act, provides an inducement for the construction of facilities urgently needed for patients suffering from chronic illness and impairments as well as an inducement to the development of diagnostic and treatment centers and rehabilitation facilities.

Federal allotments to the States were earmarked for these specific types of facilities. The act obligates the States to make a survey of need. The appropriation is available through June 30, 1957.

Following the development of the Federal regulations and their promulgation in January 1955, the States began surveys relating to the new program, and by November 32 States

AEC Control

Under the Atomic Energy Act of 1954, the distribution of all special nuclear material, source material, and byproduct material is controlled by the Atomic Energy Commission. By definition, special nuclear material refers to plutonium or uranium enriched in the isotope 233 or in the isotope 235. Source material is defined as natural uranium or thorium. Byproduct material includes all radioactive materials produced in the uranium by the process of nuclear fission and all substances made radioactive by exposure to the radiations resulting from the operation of a nuclear reactor.

Concerning control of byproduct materials, the material of interest in this discussion, the Atomic Energy Act of 1954 also states that "no person may transfer or receive in interstate commerce, manufacture, produce, transfer, acquire, own, possess, import, or export any byproduct material," except under a license issued by the AEC. The act further states: "The Commission shall not permit the distribution of any byproduct material to any licensee, and shall recall or order the recall of any distributed material from any licensee, who is not equipped to observe or who fails to observe such safety standards to protect health as may be established by the Commission or who uses such material in violation of law or regulation of the Commission or in a manner other than as disclosed in the application therefor or approved by the Commission."

The necessity of obtaining a license before purchasing radioactive materials from the AEC or its licensees has been extended by the commission to cover radioactive materials produced in particle accelerators, providing these machines were built fully or in part with Federal funds. (Particle accelerators are important because in them it is possible to produce radioisotopes which cannot be formed in a nuclear reactor.) If an accelerator is built with private funds, however, the AEC has no authority over the isotopes so produced, nor has it any say in controlling radiation levels around the accelerators while they are in operation. The Nuclear Science and Engineering Corporation recently announced the inauguration of the first private program for the production and supply of cyclotron-produced isotopes (a cyclotron is one

type of particle accelerator). Procurement of these materials from this firm will not require AEC licensing or approval. Of course, interstate shipments of these materials will have to meet regulations governing the transportation of radioactive substances.

State Responsibilities

The Atomic Energy Act in no way interferes with the power of the States to promulgate necessary or desirable rules and regulations. Since there is now at least one source of radioisotopes not subject to AEC control, and since such sources of radiation as X-ray machines and radium salts never have come under commission control, it may be that rules and regulations will have to be set up. When and if this is done, every effort should be made to maintain conformity with the recommendations of the National Committee on Radiation Protection and the requirements of the Atomic Energy Commission in order to avoid the chaotic situation that would result from 48 sets of incompatible regulations.

The Atomic Energy Commission, by virtue of its years of experience and the tremendous amount of research it conducts, is far better equipped than the individual States to formulate standards for maximum permissible concentrations in air and water, and for maximum permissible exposures to external radiation. But the State agencies can better carry on the actual regulatory and inspection functions. The commission performs these functions at present only because, having been directed to encourage the peacetime development of atomic energy, it felt it mandatory to safeguard the public health in the process. It is highly probable that the commission will be willing to relinquish much of this responsibility whenever a State agency demonstrates its readiness and ability to accept it.

The logical development of the regulation of isotope users would be the emergence of a relationship between State and local agencies and the Atomic Energy Commission parallel to that between the State and local health agencies and the Public Health Service. Where particular situations arise requiring specialized knowledge or facilities, the Atomic Energy Commission is available for consultation and assistance.

ourselves. We shall have to plan carefully: How much? how long? and how fast?

The basic program requirements for hospital and medical facilities have been affected by significant changes in the levels of hospital utilization and by reduction in the length of stay resulting from improvement in treatment and new medical discoveries. We shall need to plan wisely in relation to changes resulting from improvements and discoveries.

Fortunately, the 84th Congress has made available hospital research grant funds. These present opportunities to solve a host of hospital and related health problems through common effort. I would say that nothing is more needed than research on what is good care and what quantity of it is needed.

Food and Drug Projects Of Interest to State Health Officers

8 **By Jack M. Curtis, Ph.D.**
Assistant Chief,
Division of Pharmacology,
Food and Drug Administration

Many programs of the Food and Drug Administration follow lines that are identical with the interests of State health officers. My purpose is to outline some of these programs as a means of directing attention to areas of mutual interest. This may help State health officers to exploit the resources of the Food and Drug Administration in their work of protecting public health.

Protection Against Poisoning

One of the primary concerns of the Food and Drug Administration has been protection against poisoning—the acute, obvious poisonings contemplated by the Caustic Poisons Act as well as the chronic, subtle poisonings that may arise through the inclusion of chemicals in foods.

A growing concern over the public health hazards of numerous industrial and household chemicals is reflected by the activity of many national health organizations. The increasing number of the various household products containing hazardous chemicals makes it difficult for the family physician to keep abreast of the toxic substances and to recognize them by trade name.

The American Academy of Pediatrics, local health officers, the Food and Drug Administration, and the Public Health Service are working toward the formation in many large cities of poison centers that will accumulate data concerning the poisons that most frequently cause disastrous results. The centers will be ready on a 24-hour basis to advise physicians as to the type of antidoting that is appropriate.

In conjunction with the American Association of Medical Record Librarians, the Food and Drug Administration is studying methods whereby pilot studies can be set up in hospitals for the purpose of reporting untoward effects caused by therapeutic agents.

All of this information will help in pinpointing the toxic substances that are most important, in recommending more informative labeling, and in producing the basic data necessary to support any modification of existing laws.

We are also interested in the type of poisoning—to use the word in its broadest sense—which is caused by the misuse of potent drugs, particularly barbiturates and amphetamines. The problem is what can we do about the excessive use of barbiturates, resulting in suicides, accidental deaths, moral degeneration, or about the chronic use of excessive amounts.

It is illegal to sell these potent drugs except as directed by the prescription of a licensed practitioner. Only a very small number of pharmacists dispense the drugs indiscriminately. A still smaller number of physicians contribute to their pernicious misuse. But distribution outside licensed drug channels is increasing. In terms of the number of doses, the outlet by these various sources is tremendous.

The Food and Drug Administration investigates the illegal actions of druggists or physicians only on information from physicians, local police departments, health officers, or the

have had their plans approved for hospitals and 25 States for medical facilities.

The 1954 legislation is designed to emphasize the planning and construction of hospital-related medical facilities. Despite the increase in general hospital beds, people suffering from prolonged illness still had difficulty in obtaining care in facilities adequate to meet their needs and within their ability to pay. The need for less expensive facilities is, of course, only an indication of increasing requirement for such facilities. The demand stems from the aging of our population and its consequences in terms of increases in chronic diseases.

Present Developments

The 25 State plans for medical facilities reflect an interest on the part of the States in coordinating hospitals and medical facilities. Certain categories which represent services rather than definable units, such as a hospital or nursing home, present problems, which will ultimately be solved as experience is gained.

For the most part, diagnostic and treatment centers are being planned in relation to general hospital service areas.

It is evident that a significant amount of services to ambulatory patients is being provided in hospitals, clinics, and public health centers, particularly the specialized clinics for psychiatric, cancer, heart, dental, and tuberculous patients. In an effort to bring basic general hospital services to the patient in his own community, most of the State plans provide for diagnosis and treatment centers initially in general hospitals or as an expansion of the outpatient departments.

The more specialized services are being planned in centers where there are large general hospitals and a concentration of population. The States are still groping for the solution in communities too small to support a general hospital. Only a few States are making provisions for free-standing diagnostic and treatment centers in such communities. With few exceptions, the State planning agencies recognize the tentative nature of the planning for diagnostic and treatment centers. They propose with experience to refine this aspect of their program in subsequent annual revisions.

Because a specific unit can be defined, the nursing home category seems to present less of a problem. Nevertheless some problems have appeared.

In most States the nursing home operators have felt that licensing by the State is evidence of meeting the required standards. The problem of interpreting what is meant by skilled nursing care is still with us. Planning for nursing homes, like that for diagnostic and treatment centers, is taking place in relation to the general hospital service area. Some criticism has developed with respect to the range of the bed ratio adopted for nursing homes. The majority of State plans use 3 beds per 1,000 population, but some groups believe this ratio is unrealistically high.

The problems with respect to chronic disease hospitals have not been as difficult because the States have had some experience. In some State plans, facilities previously designated as chronic disease hospitals are now shown as nursing homes. There is evidence of increasing development of means of distinguishing between chronic disease hospitals and nursing homes and of defining the services in each. Planning in this category is primarily centered on development of services for the chronically ill in large general hospitals.

With respect to rehabilitation facilities, the inventories fail to reflect the total rehabilitation resources within the States. Often occupational therapy and physiotherapy in hospital clinics are not identified.

Rehabilitation facilities for the most part are being programed at medical schools and medical centers. The majority of State plans, however, allocate all the facilities permitted under the ratios in the Federal regulations for this category. This may not be realistic. It would seem that comprehensive rehabilitation facilities as programed at universities and medical centers would be the more reasonable solution since, in our present state of knowledge, it is important to train rehabilitation workers.

Need for Wise Planning

We need to develop understanding about these new programs—in the States as well as among

should be aware of the apparent trend of increasing amounts of antibiotics in milk.

The use of antibiotics as preservatives for food products is being investigated, for this is a field of development that may well bear careful watching.

Suggestions have been made that antibiotics be used as a spray on vegetables to inhibit rot after harvest, that chickens, after having been picked and cleaned, should be soaked in solutions containing an antibiotic to preserve them from spoilage while in transit and storage, and that antibiotics should be incorporated in the ice which is used to ice shrimp on their way to the market. None of these suggestions has been supported by sufficient experimental evidence to show that the antibiotic is not present in the food when it is consumed.

The growing practice of treating farm animals with hormones, particularly diethylstilbestrol, is justified by the economic advantage to be derived from improved quality or increased rate of growth and increased efficiency of feed utilization. Stilbestrol may be administered either in pellet form, implanted subcutaneously as is ordinarily done in chickens, or incorporated in the food as it is usually administered to cattle.

In chickens the drug causes a redistribution of fat, producing a plump, well-rounded carcass, easily and cleanly defeathered and of high quality. The effect on growth is slight. In cattle, on the other hand, the effect on growth is quite pronounced. Increases of growth of about 20 percent have been reported, along with a decreased feed consumption of about 15 percent. Usually, the carcass quality is about one grade lower.

The mechanism by which these changes take place is not clear. There is evidence that stilbestrol, whether it be fed or administered in pellet form, increases nitrogen retention in cattle. Furthermore, hypertrophy of the liver, of the adrenal glands, and of the pituitary without specific cellular changes has been reported. These observations seem to indicate a change in the endocrine gland metabolism, but exactly how these changes produce the increasing growth rate and increase in efficiency of food utilization is not clear.

The Food and Drug Administration has re-

quired the manufacturers of stilbestrol-containing feed supplements for cattle to submit extensive evidence that no added estrogen is in the edible portions of steers which have been fed these supplements. When this work was repeated in the laboratories of the Food and Drug Administration, it was shown that meat from steers fed 10 milligrams of stilbestrol a day contained not more than 0.6 parts per billion estrogenic activity when ready for market.

Therefore, it may be stated with considerable confidence that stilbestrol fed to steers under the conditions outlined by manufacturers of feed supplements will constitute no hazard as an additive to food products derived from animals thus fed.

Another problem concerns feeds prepared for small laboratory animals when the feeds have been run through mixers immediately following stilbestrol-containing feeds for steers. The result has been an accidental contamination of the small animal feeds with stilbestrol, which, in some cases, has quite serious effects upon the reproductive capacity of small animal colonies. Also, the results of hormonal assays would be erroneous if the experimental animals received this contaminated food.

The exact method of controlling such contamination and preventing its occurrence is under study by the Food and Drug Administration.

Pesticidal Residues

The basic philosophy of control of pesticidal residues was changed somewhat by the passage of the pesticide chemicals amendment in 1954. Under this law, after the Secretary of Agriculture has certified that a pesticide is useful, application may be made to the Food and Drug Administration to establish tolerances or exemptions for the chemical, supported by data to establish that these tolerances are safe to the consumer. The type of data required is of interest.

The acute toxicity of the chemical is of value in appraising the hazards to those who handle or apply it.

The biochemistry of the compound including data on its absorption, excretion, storage, and metabolism is essential in evaluating the magni-

relatives of individuals that misuse drugs. Top priority is given to reports of the illicit distribution of barbiturates.

This type of investigation is a profitable opportunity for cooperation between State health officers and the Administration. To the extent that it is feasible under State laws, we are anxious to coordinate our activities with those of the States so that the consumer can be effectively protected.

Regulating Medical Quackery

Our efforts to control medical quackery continue to be very difficult. Since the Food and Drug Act does not regulate the practice of medicine, our approach toward the control of medical quackery must be directed at the drugs or devices used in the treatment of disease. Our activity is necessarily limited to situations involving interstate shipment of drugs. The adequate control of medical quacks seems to be basically a State responsibility.

At the trial of the case against the Hoxsey Cancer Clinic in Texas, which culminated in the issuance of an injunction in October 1953, it was testified that more than 6,000 patients had come to the clinic in a 2-year period. The injunction prohibited the interstate shipment of the various drugs used in Hoxsey's supposed treatment of cancer.

More recently, a Hoxsey cancer treatment center in Pennsylvania has opened, with the backing of influential local people. Action has been taken against the center, but legal delays have slowed up enforcement results.

On November 7, 1955, the Texas State Board of Medical Examiners revoked the licenses of 6 osteopaths and 1 medical doctor associated with the Hoxsey clinic, finding them guilty of "unprofessional" and "dishonorable" conduct. Their attorney has announced he will appeal.

If the States could "nip in the bud" the promoters of fake drugs and devices, they would be serving their citizens well and at the same time they might prevent the growth of a formidable fraud.

The Electronic Medical Foundation of San Francisco consented to an injunction in March 1954 against the shipping of 13 different types

of electronic devices used for the diagnosis and treatment of serious diseases.

Among the devices was one represented as a "tuning apparatus" by which it was supposedly possible to distinguish the alleged characteristic radio frequencies associated with different diseases. Called a Radioscope, the apparatus had dials, lights, wires, and a slot in which could be placed a specimen carrier of filter paper bearing dried blood of a patient. Investigation showed that this blood diagnostic service was incapable of distinguishing the blood of animals or birds from that of man or that of the living from the dead. Diagnostic "readings" from this machine were sent to local practitioners with instructions for treatment by other machines also supplied by the foundation. More than 5,000 of the treatment machines had been distributed at the time of the injunction decree.

Antibiotics and Food

The administration of antibiotics and hormones to animals, which later will be used as food for man, is a special segment of the problem of chemical additives in food. The feeding of low levels of antibiotics to animals has not resulted in the deposition of any appreciable residue of antibiotics in the tissues of these animals, but the use of larger quantities of antibiotics for the treatment of disease, such as the treatment of mastitis in cattle by intramammary infusion, has caused concern.

This problem was recognized first in the cheese industry when starter colonies would not grow in milk collected from animals so treated.

The Food and Drug Administration found positive results of penicillin in 3.2 percent of 94 samples of milk collected throughout the United States in 1954. In 1955, 11.6 percent of 474 samples of milk from all parts of the country were found to be positive for penicillin. The actual amounts were quite small and they were regarded by authorities on antibiotics as unlikely to change oral or intestinal flora or to provoke sensitization in a nonsensitive consumer.

Although the evidence is not adequate for definite conclusions, State dairy sanitarians

Willamette Valley Chest X-ray Survey

By GORDON C. EDWARDS, M.D., M.P.H.

THE WILLAMETTE VALLEY chest X-ray survey in 1951 was the first attempt in the United States at conducting a large-scale rapid-tempo communitywide chest X-ray survey in a relatively sparsely populated, predominantly rural area. It was the 16th large-scale survey undertaken through use of the survey equipment and personnel available by loan from the Public Health Service.

This report is intended to be an objective appraisal of the findings of the Willamette Valley chest X-ray survey, based on a study of the final postsurvey diagnoses supplied by the private physicians examining survey cases referred for followup because of suspect chest X-ray findings.

A number of rapid-tempo mass chest X-ray surveys have been reported in the past, including such large-scale operations as Los Angeles, Boston, and Cleveland. A similar report, in limited publication, was made shortly after conclusion of the Willamette Valley survey by the Report Committee of the Willamette Valley Chest X-ray Survey, Inc. Survey findings in that report were based on a statistical analysis of readings of 70-mm. and 14" x 17" retake screening X-rays taken during the survey, but it lacked the essential element of clinical appraisal for definitive diagnosis. The present report includes this all-important feature.

Dr. Edwards, with the Oregon State Board of Health since 1946, has been director of the division of preventive medical services since 1950.

The survey area included eight Oregon Willamette Valley counties: Benton, Clackamas, Lane, Linn, Marion, Polk, Washington, and Yamhill. Excluded, however, were Multnomah County and its county seat, the city of Portland. The eight counties chosen cover an area of about 13,000 square miles, larger by far than many States, and contained a population

of about 520,850 persons, almost wholly white and largely American born. The region lies between the coast range on the west, the Cascade Mountains on the east, and the foothills of these two mountain ranges on the south, and is traversed through its length by the Willamette River, emptying into the Columbia River which forms the valley's northern border. It has been called the garden of Oregon and was the lode-stone that drew and still draws thousands westward to its fertile soil.

Southernmost in the valley and largest of the

tude of the hazards to the consumer when residues of the chemical remain on food. For example, it has been found that during the usual process of detoxification of heptachlor, an epoxy derivative that was produced was three times as toxic to animals as the original pesticide.

Next, the chronic toxicity of the chemical is required. This involves a 2-year feeding study in rats and, if necessary, rather prolonged studies in another species of animal, usually the dog.

Finally, there is a pathological examination of the organs of these experimental animals in order to locate the site and to determine the extent of injury produced.

All these data are then considered together to arrive at a tolerance that will protect the sick, the healthy, the young, the old. This tolerance includes a safety factor that is designed to permit a maximum intake of the chemical from all possible sources that is no greater than one one-hundredth of the largest dose that is known to produce no injury to the experimental animal.

The various tolerances as they are determined are published in the *Federal Register*, but to provide this information in a more convenient form the Administration provides a looseleaf service entitled "Summary of Tolerances and Exemptions for Residues of Pesticide Chemicals."

Diseased Poultry Inspection

The sanitation of poultry dressing plants and the antemortem and postmortem inspection of poultry to eliminate diseased birds from channels of commerce are problems that have been considered before by the Association of State and Territorial Health Officers.

An advisory panel of outstanding poultry pathologists and research workers has met with members of the Food and Drug Administration and the Public Health Service to make recommendations regarding inspection procedures and the disposition of diseased poultry. As a result, there is in preparation a manual of inspection procedures.

Civil Defense Activities

The food and drug program relating to civil defense has been developed along educational and technical lines. Courses of instruction in methods of inspection when contamination with radioactivity is suspected are now being given throughout the country and will be continued throughout fiscal 1956. Each of our 16 districts has been supplied with the necessary items of equipment to measure radioactive contamination and has been instructed in their use.

Representative samples of both food and drugs have been exposed to atomic blast to determine its effect on them. In only two drug products, insulin and vitamin B₁₂, did the potency deteriorate. Glass containers were discolored and, if close enough to the blast, became radioactive. Since studies of the food exposed more recently have not been completed, about all that can be said is that the foods have an off taste. When radioactivity was induced it seemed to be related to the phosphorus concentration in the food. Further feeding studies are under way.

. . .

NOTE: Since this paper was delivered, evidence has been submitted to prove the absence of a chlortetracycline residue in cooked but not in fresh poultry which had been chilled in water containing 10 p.p.m. of the antibiotic.

in the report, "Viewing the Valley," published by the Willamette Valley Chest X-ray, Inc., in 1952. The Public Health Service supplied 18 mobile X-ray units, film, processing materials and operating personnel, physicians to read films, clerical staff for record and statistical services, and consultation. In addition, two X-ray units of the Oregon State Board of Health, with operating personnel, participated in the survey, and many professional and lay

individuals at both State and local levels participated on a full-time or part-time basis.

Each of the eight participating counties was separately and independently organized, each with its own county executive committee and chairman. The medical society, health department, and tuberculosis and health association in each county served as sponsoring agencies, inviting the active participation and help of all other groups, agencies, and individual citizens

¹ Estimated number X-rayed varies slightly from totals in tables 3 and 5, which are enumerated by the survey units. Discrepancies are mainly due to loss of approximately 850 registration cards in Clackamas County.

² These percentages are decreased by inclusion of the under age 15 group, who were X-rayed only on specific request of, and referral from, a physician.

survey counties in area and population is Lane County with its city of Eugene, home of the University of Oregon. Lying north of Lane are Linn, Benton, Marion, Polk, Yamhill, Washington, and Clackamas Counties, the latter two extending to the Portland metropolitan area. Corvallis, county seat of Benton County, is the site of Oregon State College, while the Oregon College of Education is located at Monmouth in Polk County. Salem,

the State capital, is also the county seat of Marion County. The outline map of Oregon shows the survey area and the populations of the counties involved.

The Operation

The actual survey operation time was between July 17 and October 24, 1951. Details on planning and operation of the survey were given

was checked. This sample served as a basis for studying the suspect cases reported through 14" x 17" film retakes and the diagnosed cases reported through epidemiological followup. General makeup of the participating survey group with respect to age and sex, by county, is shown in tables 1 and 2, and breakdown of the total valley population by age and sex is shown in table 7.

Statistical Analysis

The 1950 census of the 8 valley counties showed a combined population, age 15 years and over, of 375,815. The total of 237,229 70-mm. films taken during the survey would indicate a coverage, ignoring duplications and nonresidents, of approximately 63 percent of those eligible (table 3).

A total of 7,415 small films were read as showing abnormalities. Of these 4,222 were suspect tuberculosis, 2,846 other chest pathology and 347 suspect cardiovascular disease. Twenty-two of the 7,415 were duplications, which left 7,393 individuals for recall to retake centers (table 3).

Seven hundred seven individuals of the 7,393 recalled did not respond. Small films of these persons were reviewed, and 206 were classified as not sufficiently significant to warrant further followup. One hundred seven, who were visitors to the area or had moved since X-ray, were referred to the health departments of their jurisdictions for followup, and 192 were referred to valley health departments. The remainder were found already under care, or referred to physicians or State institutions, or were deceased (table 4).

A total of 6,822 individuals returned for retakes, including 136 with unsatisfactory or negative 70-mm. films. Of these, 6,560 had confirmatory 14" x 17" films taken while 262 received cardiac interview only, with referral to their physician (table 3).

Out of 6,560 confirmatory 14" x 17" films taken, 11 were technically unsatisfactory and were referred for further followup. An additional 2,766 individuals were referred for further study on the basis of X-ray interpretation, 1,264 for tuberculosis and 514 for suspect tuberculosis. The remaining X-ray referrals were 988 for other chest diseases including 89 cardio-

in the community. Valleywide coordination and cooperation was obtained by setting up the Willamette Valley Chest X-ray Survey, Inc., with headquarters in Salem and a board of directors consisting of the chairmen of the principal valleywide committees and the general chairman from each participating county, plus State representation from the Oregon State Board of Health, Tuberculosis and Health Association, Heart Association, and Cancer Society. A survey director for the entire valley was appointed to direct and coordinate operations.

The Policy

Overall survey policy was established by the executive committee and board of directors of Willamette Valley Chest X-ray Survey, Inc. Professional policy regarding criteria for interpretation of X-ray films, criteria for recall for 14" x 17" film retakes, interview procedures in retake centers, and referral methods were developed by a Professional Policies Committee, with representation from the county medical societies and health departments involved and chaired by a member of the Tuberculosis Committee of the Oregon State Medical Society.

All suspect chest pathologies except cardiovascular were recalled for 14" x 17" film recheck. All suspects on 14" x 17" film retakes were referred to their private physicians for further study and definitive diagnosis. Epidemiological followup was a responsibility of the local health department in the area of residence of the suspect. Chest pathology other than tuberculosis was followed only to the point of establishment of medical consultation although all physicians of referral were queried through a specially developed epidemiological report form to obtain final diagnosis. Diagnoses other than tuberculosis were supplied by physicians on a purely cooperative basis since the majority of conditions involved (such as neoplasm and heart disease) are not reportable in Oregon.

The Population Involved

The aim of the survey was to obtain a chest X-ray of every person in the valley 15 years of age and over. Children under age 15 were X-rayed only on specific request and referral from a physician.

To determine the makeup of the population X-rayed, every tenth registration card of all individuals registered for 70-mm. film X-rays

Table 7. Population participation,¹ active tuberculosis cases, and neoplasm cases, by age and sex, Willamette Valley chest X-ray survey, 1951

¹ These data are based on a 10-percent sample of original report cards. Estimated numbers X-rayed vary slightly from totals shown in tables 3 and 5, which are totals enumerated by the survey units. Discrepancies are mainly due to loss of approximately 850 registration cards in Clackamas County.

² Percentages are decreased by inclusion of the under age 15 group, who were X-rayed only on specific request of, and referral from, a physician.

vascular. Reported essentially negative were 1,986 (tables 3 and 4).

Of the 2,777 individuals referred for further study, a total of 2,234, or 80.4 percent, were followed to completion of diagnosis (table 5). The remaining 543 individuals were followed by field visit, mail query, and by contacting the physician named at time of X-ray, but for various reasons, such as moving out of area, non-cooperation, and death, final diagnosis was not obtained. Completion of followup to diagnosis varied from 73.2 percent in Marion County to 92.1 percent in Clackamas.

Final diagnosis on the above 2,234 individuals, as supplied by the attending physician, is shown by county in table 5. Diagnosis was accepted only on signed report of the attending physician and no case was tabulated as tuberculosis on the basis of X-ray interpretation or positive sputum findings, or both, without clin-

ical appraisal and report. An arbitrary cut-off date of 2 years postsurvey was adopted, and survey cases reported after this date were not credited to the survey. Only previously unreported active tuberculosis cases were credited to survey discovery.

On these bases there were 131 previously unknown active pulmonary tuberculosis cases reported and 125 neoplasms. One hundred twenty individuals, including 90 with activity undetermined at time of report and 30 arrested or inactive less than 2 years, were also reported and added to the tuberculosis followup register. In addition, 542 individuals were reported for other miscellaneous chest diseases and 26 for cardiovascular disease.

Table 5 shows by county the yield of newly discovered active tuberculosis cases and neoplasms per 1,000 70-mm. films taken. On the basis of 237,229 70-mm. films for the entire val-

the low overall participation in Clackamas County may largely nullify the comparative case-finding results in that county in view of the claim by some that the proportion of positive tuberculosis findings increase as coverage approximates 100 percent of eligibles. Further study of findings by age group and sex by county may prove of value.

The arbitrary 2-year diagnostic followup and report period, adopted to permit as full a completion of diagnostic study and completion of reporting as reasonably possible, doubtless does have a tendency to increase the ratio of moderately and far-advanced cases over minimal. Stage of disease of all survey cases at time of reporting is shown by county in table 8. Of the 131 reported active cases, approximately 24.5 percent were reported as minimal, and 64.1 percent as moderately advanced. Only 13 cases in all, or 9.9 percent, were reported as far advanced. In 1.5 percent the stage of disease was not indicated. These figures compare favorably with available Oregon data on routinely reported pulmonary cases for 1953, which show of 320 such cases only 15.3 percent were minimal, 36.6 percent moderately advanced, and 26.2 percent far advanced. In 21.9 percent, the stage was undetermined.

At the time of registration for miniature chest X-ray, a history was obtained of the length of time since previous chest X-ray. Among the tuberculosis cases diagnosed, almost

one-fourth had had no chest X-ray in 5 years, while an equal number had never had a prior chest X-ray. Among neoplasm cases, 20 percent had had no chest X-ray in 5 years, while one-third had never had prior chest X-rays. Exact figures according to diagnosis are shown in table 9. Considering all diagnoses together, almost exactly one-half the cases had no prior X-rays or had none within 5 years.

Conclusion

Results of this survey definitely indicate the value of mass chest X-ray of apparently healthy people. The discovery of slightly more than one previously unknown active case of tuberculosis for every 2,000 participants would alone justify the survey without considering the cases of neoplasm and cardiovascular and other chest diseases revealed as an extra dividend. It is recognized that other procedures such as routine chest X-ray of hospital admissions will reveal higher numbers of cases per 1,000 chest films, but such surveys dealing with ill people are complementary and not a substitute for surveys of the apparently well. Cases discovered before symptoms force medical consultation are found in earlier stages of disease although many suspects screened by routine chest X-ray go a distressingly long time before final definitive diagnosis.

ley, 0.55 active tuberculosis cases and 0.53 neoplasms were found for each 1,000 small films. The 899 individuals referred on 70-mm. and 14" x 17" films for other chest diseases, and approximately 351 for cardiovascular disease, undoubtedly included many with previously undiagnosed conditions who benefited by further study, but no attempt is made to tabulate or break down for further study these cases reported.

As might be expected, significant differences were revealed for diagnosis of tuberculosis and neoplasms in individuals of various age groups and different sex. Variation was also found in occurrence rates in different counties. Break-down of physician diagnosis by age and sex is shown in table 6, while table 7 shows the find-

ings of active tuberculosis and neoplasms by 10-year age groups, and the number of cases per 1,000 small films taken of participants. cursory examination reveals that while the survey participation was poorest in the age group 65 and over the returns per 1,000 70-mm. films taken were highest in this group both in active tuberculosis cases and neoplasms found. This would seem to indicate a need for increased emphasis on the older age groups in future surveys.

Clackamas, Linn, Marion, and Yamhill Counties seemingly had the highest overall tuberculosis case yields. The relatively high rate per 1,000 miniature films may be particularly significant in Marion County in view of the low percentage of completed followup. Similarly,

available awards, which should benefit not only the public health worker who may wish to compete but also those persons or groups who may wish to establish new awards. It would be fitting for new awards to be created for achievements in administration, program accomplishment, and communication.

Omitted from the tabulations are the following categories of honors: (a) those not primarily intended for workers in the field of public health although from time to time those awards may be given to individuals who are also

active in public health; (b) those given for length of service or length of membership; (c) those given for published papers describing research as distinct from those for the research itself; (d) those given to former officers and members for service to the organization; (e) election to Delta Omega or to other honorary societies; (f) scholarships and fellowships; (g) honorary lectureships.

[*Public Health Reports* welcomes supplementary information which may be used in possible future revisions of this tabulation.—ED.]

Public Health Awards

Name, sponsor, and administrator ¹	Type ²	Eligibility for award	Basis
American Hospital Association Award of Merit. American Hospital Association (S, A).	Medallion and scroll	Hospital administrators.	Outstanding accomplishments in the hospital field and in improving hospital care.
American Occupational Therapy Association Award of Merit. American Occupational Therapy Association (S, A).	Citation certificate; number not fixed.	Members -----	Outstanding service to field.
Anderson Service Award. American Association for Health, Physical Education, and Recreation (S, A).	Certificate; no more than 6 per year.	Nonmembers -----	Outstanding contributions to field; may be general educator or doctor.
Axson-Choppin Award. Louisiana Public Health Association (S, A).	Plaque	Citizen not connected with health department.	Outstanding contributions to health progress in State.
Bell Award. National Association for Mental Health (S, A).	Trophy	Newspapers -----	American daily newspaper which during the preceding year had made an outstanding contribution in the fight against mental illness.
Biggs Medal. New York State Public Health Association (S, A).	Medal -----	Public health workers.	Contribution to public health.
Blakeslee Award. American Heart Association (S, A).	\$500 each and scroll. Generally 4 given —1 each for newspapers, magazines, books, and radio and television.	Authors, newspaper writers, producers, publishers, and so on.	Creative efforts in any medium of mass communication judged to have contributed most to public understanding of the progress in research and in the prevention, care, and treatment of heart and circulatory diseases.
Borden Awards. The Borden Company (S): American Home Economics Association (A).	\$1,000 and gold medal.	Members.	Fundamental research in the field of nutrition and experimental food, reported in public documents or official journals.
American Institute of Nutrition (A).	do -----	do -----	Distinctive research which has emphasized the nutritive significance of the components of milk or of dairy products.
American Veterinary Medical Association (A).	do -----	do -----	Outstanding research contributing to dairy cattle disease control.
Bruce Memorial Award. American College of Physicians (S, A).	\$250, bronze medal, and travel expenses.	Anyone -----	Outstanding accomplishments and contributions in the field of preventive medicine.

Public Health Awards

By HOMER N. CALVER, B.S.

NEARLY 50 awards are given regularly in the field of public health, most of them annually. They are administered through more than 30 national, State, and local organizations. With few exceptions these awards go to individuals and are presented at the annual meeting of the administering organization.

In addition to the scroll, plaque, medal, certificate, or trophy which the winner receives there is sometimes an honorarium, ranging in value from \$50 to \$2,500. The presentation ceremony usually includes a résumé of the recipient's career and references to the accomplishments that brought him the award.

An analysis of these public health awards (see table) was undertaken by the Public Health Committee of the Paper Cup and Container Institute when it decided to establish an award in the memory of Dr. Samuel J. Crumline. The study revealed that there were no national awards for health departments. This was surprising because of the emphasis on teamwork in public health and the fact that the full-time local health unit has long stood as the symbol of the most desirable vehicle for community public health service.

As one reads the statements which outline the basis for selecting winners of the several awards, there is a notable repetition of the nouns: contribution, service, achievement, accomplishment. They are used in nearly all possible

Samuel J. Crumline

Dr. Samuel J. Crumline's distinguished career included service as the first full-time health officer of Kansas and director of the American Child Health Association. Among his pioneer contributions were the crusades he organized against flies and against the common drinking cup and spitting in public places and water pollution. His achievements were, therefore, not only those of an outstanding administrator but those of a leader in the fight for sanitation. Moreover, the impact of his work had been achieved through methods which eventually became an inherent part of what subsequently was called "health education." He died at 91, at which time he was a consultant on the staff of the Paper Cup and Container Institute.

combinations with these adjectives: meritorious, outstanding, distinguished, exceptional, signal, significant, distinctive. The Pennsylvania Public Health Association, with a refreshing variation of terminology and criterion, offers an award for "enthusiastic leadership."

The awards place considerable emphasis on accomplishments in the field of research, with a corresponding neglect of recognition of administrative and program accomplishments. This, too, is surprising in a field which is essentially one of applied science.

These and similar observations concerning the existing awards led the Public Health Committee of the Paper Cup and Container Institute to conclude that the Crumline Award might be useful if it were made to health departments and the winners were judged on evidence of teamwork within that department and with community groups.

The accompanying table gives an analysis of

Mr. Calver, secretary of the Public Health Committee of the Paper Cup and Container Institute, is editor of the Health Officers News Digest. Robert E. Mytinger, assistant to the secretary, made the tabulations.

Name, sponsor, and administrator ¹	Type ²	Eligibility for award	Basis
Lasker Award. Albert and Mary Lasker Foundation (S). International Society for the Welfare of Cripples (A).	\$1,000 and statuette triennially; number not fixed.	Lay or professional.	Achievement in the development of services for the physically disabled.
Massachusetts Association of Sanitarians Scroll. Massachusetts Association of Sanitarians (S, A).	Scroll.	Sanitarians.	Massachusetts sanitarian who in past year did most to enhance the status of the association and public health work.
National Society for Medical Research Citation. National Society for Medical Research (S, A).	Citation certificate; 1-3 per year.	Unrestricted.	Contribution to public understanding of medical science.
New York State Public Health Association Health Education Information Citation. New York State Public Health Association (S, A).	Citation certificate; 3-4 per year.	Newspaper, radio or television station.	Contribution to better understanding of health matters.
North Carolina Public Health Association Award of Merit. North Carolina Public Health Association (S, A).	Citation certificate.	Group of members associated in some accomplishment.	Outstanding contributions or activities during past year for a local health department or group.
Nutting Award. National League for Nursing (S, A).	Medal and scroll; 1 every other year.	Public health workers—official, non-official.	Outstanding contribution to community welfare through nursing education, nursing service, or through some other areas of public health.
Pan American Gold Medal. National Society for the Prevention of Blindness (S, A).	Medal; 1 every 4 years.	Medical and non-medical public health workers.	Significant contribution to prevention of blindness.
Pennsylvania Public Health Association Award of Merit. Pennsylvania Public Health Association (S, A).	Citation certificate.	All public health workers.	Distinguished service and outstanding contributions to the advancement of public health.
Pennsylvania Public Health Association Honorary Membership. Pennsylvania Public Health Association (S, A).	Scroll; 2 per year.	do.	Enthusiastic leadership in public health work.
Pickett-Webb Memorial Award. Utah Association of Sanitarians (S, A).	\$50 and scroll.	Sanitarian.	Outstanding achievement in field in the State of Utah.
Prentiss Award. Cleveland Health Museum (S, A).	Citation certificate.	Health educator.	Outstanding achievement in health education field.
Public Health Association of New York City Award of Merit. Public Health Association of New York City (S, A).	Certificate in each category.	All public health workers.	Meritorious service to public health in fields of medicine, dentistry, nutrition, nursing, laboratory service, statistics, administration, social work, health education, environmental sanitation.
Public Health Association of New York City Outstanding Service Award. Public Health Association of New York City (S, A).	Plaque.	do.	Outstanding service to public health in New York City.
Rankin Award. North Carolina Public Health Association (S, A).	Trophy.	Members.	Outstanding contributions to public health in North Carolina over period of several years.
Reynolds Award. North Carolina Public Health Association (S, A).	do.	do.	Outstanding contributions to public health in North Carolina, meritorious service above and beyond the call of duty.

Name, sponsor, and administrator ¹	Type ²	Eligibility for award	Basis
Crumbine Medal. Kansas Public Health Association (S, A)	Medal... ..	Lay or professional	Outstanding contribution to health of the people in Kansas. May be a native Kansan who has made major contribution while in another State. Regional or national recognition is desirable.
Crumbine Award. Public Health Committee of the Paper Cup and Container Institute (S, A).	1 plaque and medals as merited	Health unit, health officer and person or persons in unit most directly responsible	Outstanding achievement in the development of a comprehensive program of environmental sanitation.
Crumbine Award. Public Health Committee of the Paper Cup and Container Institute (S, A).	...do...do... ..	Outstanding achievement in the development of a program of eating and drinking sanitation.
Cummings Memorial Award. American Industrial Hygiene Association (S, A).	\$100 for paper at banquet and plaque	Industrial hygienist	Outstanding contributions to the knowledge and practice of the profession of industrial hygiene.
Dana Gold Medal. St. Louis Society for the Blind (S). National Society for the Prevention of Blindness (A).	Medal.....	Medical and non-medical public health workers	(a) Long meritorious service for conservation of vision, for prevention and care of diseases dangerous to eyesight, or (b) research and instruction in ophthalmology and allied subjects, or (c) social service for the control of eye diseases.
Florida Association of Sanitarians Scroll. Florida Association of Sanitarians (S, A)	Scroll.....	Sanitarians	Outstanding accomplishments in the field of sanitation.
Gold Heart Award. American Heart Association (S, A).	Scroll and pin, 1 to physician, 1 to layman.	Physician, business, or public health leader.	Outstanding contributions to the advancement of cardiovascular medicine or the heart program.
Gulick Award. American Association for Health, Physical Education, and Recreation (S, A).	Medal.....	Members or non-members	Outstanding contributions to field.
International Association of Milk and Food Sanitarians Award. Five detergent manufacturers (S). International Association of Milk and Food Sanitarians (A)	\$1,000 and citation certificate	Sanitarian attached to local health department	Outstanding service and meritorious accomplishment in field of sanitation.
Johnson Annual Award. Missouri Public Health Association (S, A)	Scroll... ..	Professional public health worker or layman.	Any person who has made an outstanding contribution to public health in Missouri.
Kimble Award. The Kimble Glass Company (S). Conference of State and Provincial Public Health Laboratory Directors (A)	\$500 and citation certificate	Lab personnel	Contributing outstandingly to developing a new and better method in the field of public health.
Lasker Award. Albert and Mary Lasker Foundation (S). American Heart Association (A).	\$1,000, scroll, and statuette	Physician or scientist	Outstanding scientific contribution in the field of cardiovascular research.
Lasker Award. Albert and Mary Lasker Foundation (S). American Public Health Association (A)	\$1,000 and a statuette. Occasionally a special individual award of \$2,500, scroll, and statuette to groups, 4-10 per year	All categories of public health workers. Individuals or groups—official or voluntary.	Outstanding achievements in either research or in administrative application of research in the control of diseases that are recognized as major causes of death.

Public Health Research in Chronic Disease

By JOHN E. DUNN, Jr., M.D.

THE changing nature of the health problems that burden our society is becoming increasingly apparent. The severe outbreaks and epidemics of the infectious and communicable diseases are giving way to the endemicity of chronic disease.

"Chronic disease" as a generic term usually conjures up such entities and groups of diseases as heart disease, cancer, mental diseases, and diabetes. Actually, the connotation is broader than the mere disease label. There is the added implication of insidious progression, slow and incomplete recovery, disability, necessity for adaptation on the part of the affected individual, and the host of services—medical, nursing, social, economic, housekeeping, rehabilitation—involved in the struggle between an individual and a chronic disease from which he is trying to recover or with which he is learning to live. A definition adopted by the Conference on the Preventive Aspects of Chronic Disease in 1951 (1) states that "chronic disease comprises all impairments or deviations from nor-

mal which have one or more of the following characteristics: (a) are permanent; (b) leave residual disability; (c) are caused by nonreversible pathological alteration; (d) require special training of the patient for rehabilitation; and (e) may be expected to require a long period of supervision, observation, or care." Although one might wish to quibble with some of the details of this definition, it paints the picture of chronic disease essentially as seen through the eyes of the victim. The summation of such victims in a community delineates the problem of public health.

A definition of chronic disease has been considered; it would seem unnecessary to define research. Here too, however, there are differences of opinion as to what should be included in the term. Such modifying adjectives as "applied," "field," "clinical," "epidemiological," and "administrative" are used to distinguish the fuzzy limits of what can be encompassed by so jealously guarded a term as research. If we consider research as a quest for knowledge and view the chronic disease problem from the vantage point of public health responsibility, we are immediately impressed with the fragmentary nature of knowledge and the rather general ignorance of the whole spectrum of chronic diseases and their chronology from etiology to recovery, symbiotic stabilization, or death. In this discussion research in chronic disease is considered in its broadest sense and from the standpoint of public health responsibility. Since I am working in the can-

Dr. Dunn is a field investigator with the Field Investigations and Demonstrations Branch of the National Cancer Institute, National Institutes of Health, Public Health Service, assigned to the bureau of chronic diseases, California State Department of Public Health. This paper was presented at the 1955 meeting of the Western Branch of the American Public Health Association, Phoenix, Ariz.

Chlortetracycline as a Preservative

The antibiotic chlortetracycline may now be used as a preservative for uncooked poultry. First marketed as aureomycin, the chemical will be sold under the trade name Acronize chlortetracycline. The Food and Drug Administration ruling, announced November 30, 1955, marks the first time an antibiotic has been permitted in food processing.

According to submitted data, chlortetracycline, added to the water in which the poultry is chilled after dressing, retards development of spoilage organisms and thereby prolongs the freshness of the poultry. Effectiveness of the process depends upon its application to clean, freshly killed birds.

FDA has set a tolerance of 7 p.p.m. for residue of chlortetracycline remaining in any portion of the uncooked bird. FDA's decision was based on evidence that cooking destroys this amount of chlortetracycline so that none is left when the poultry is served.

Permission was granted in accordance with provisions of the Miller amendment to the Federal Food, Drug, and Cosmetic Act, which authorizes the fixing of tolerances for pesticide residues on raw agricultural products, provided there is suitable evidence of usefulness and of the safety of the permitted residues. With this exception, FDA has not changed its basic position that the law bans the use of antibiotics in human food.

disease problem and partly from the lack of research equipment and techniques having the precision and accuracy of those available to the laboratory investigator. I am referring to the epidemiological study of chronic diseases. Man is a complex animal who has evolved a complex and largely artificial social structure within which to live. Not all economic and technological progress is necessarily good for him in a biological sense. He eats too much, smokes too much, drinks too much, and lives under too much tension. Evidence is accumulating to indicate that these, and other factors much less obvious, play a part in the occurrence of chronic disease. Epidemiologically speaking, then, the soil should not be neglected in preoccupation with the seed. Epidemiology is primarily a tool of public health.

Cancer has perhaps received more attention, meager and superficial as it has been, than any of the other chronic diseases regarding the characteristics and attributes of people that are related to the occurrence of the disease. Most of this comes under the classification of descriptive epidemiology and has perhaps served to raise more questions than it has answered. Much of what has been learned in cancer epidemiology, or endemiology as some would prefer to call it, has had to come from existing data, such as mortality records, or from short-term retrospective studies that could be handled with limited finances. Nevertheless, some rather clear-cut and specific findings have come out of such investigations, such as bladder cancer as a result of beta-naphthylamine exposure in the aniline dye industry, chromate cancer in the chromate industry, the direct relationship of the amount of solar radiation and the frequency of skin cancer, the relative immunity of Jewish women to cervical cancer, and, more recently, the association of cigarette smoking and lung cancer. Other established associations are in need of further explanation. Cancer of certain sites has been shown to exhibit a socioeconomic gradient. For example, cancer of the upper gastrointestinal tract and stomach and cancer of the cervix show an increasing incidence as economic status decreases. A gradient in the opposite direction is shown by cancer of the breast and ovary. These findings originated from studies carried on in England and,

later, in Denmark. Recently, studies to determine the existence of such gradients in this country have been undertaken, one of which is nearing completion for San Francisco. The findings of these several studies differ in certain details but confirm the fact that cancer of certain sites does have socioeconomic gradients.

Isolated studies concerning cancer of the cervix have shown association of this disease with a multiplicity of variables, including the fact of marriage, age at marriage, childbearing, economic status, stability of marriage, syphilis, circumcision of spouse, and race. Certainly, there is need and opportunity for unraveling this multiplicity of variables, many of which are correlated with each other.

Recently, there has been a trend toward use of the more expensive and time-consuming, but much more satisfactory, prospective type of epidemiological approach. Perhaps this indicates a more general realization of the contribution that the methods of epidemiological study can make to the problems of the chronic diseases. The findings relative to cigarette smoking and lung cancer have been confirmed by such studies in both this country and England (5, 6). A byproduct of considerable importance from both of these studies was the finding that cigarette smoking is also associated with coronary heart disease. A finding such as this could not, of course, come from a retrospective study of lung cancer patients. A study is now under way in California in which the lung cancer risk of certain occupations is being determined. A previous study of the case-control type indicated that certain occupations carried an increased risk of lung cancer. At the present time, populations of workers engaged in these suspect occupations are being assembled, and their lung cancer experience will be determined over the next several years by checking all cancer deaths among males occurring in the State against these assembled populations.

It was determined that populations of 5,000 to 10,000 individuals would be necessary in order to have a reasonable expectancy of lung cancer mortality during the study period. Data on such large numbers would be difficult to collect from industrial establishments, and mailed

cer field, I will draw on that subject for illustrative purposes.

Areas of Research

Chronic diseases and conditions are problems of public health for one or more of the following reasons: (a) their relative importance as causes of death; (b) their responsibility for prolonged disability, during which time the affected individual is not self-sufficient, with all that this implies; and (c) the ability of the community, through organized effort, to meet many of the problems that are difficult or insoluble for the individual.

Public health has a need of knowledge of the whole chronology of chronic disease, from the characteristics, habits, and surroundings of individuals that give them a special proclivity for a certain disease or diseases, as, for example, current interest in obesity and cigarette smoking, to the requirements of the individual with stabilized disease which will return him to an active, useful life. The chronology of chronic disease for the purpose of this discussion can be conveniently, although somewhat arbitrarily, divided into the following stages: (a) the pre-disease period, during which the unknown and suspected etiological factors are operating; (b) the incipient stage, when the disease is recognizable by some clinical or laboratory means but is not yet symptomatic; (c) the full-blown symptomatic stage; (d) stabilization of the disease process and maximal recovery; and (e) restoration of the patient to useful life. The first two stages are the most appealing to preventive medicine and public health and the actual or potential means for attacking chronic diseases at these stages have been designated primary and secondary prevention, respectively (1). The third stage, of course, is the period for skilled medical management. The fourth and fifth stages are periods when the individual is in greatest need of assistance and services from various community resources, that may or may not exist, in his effort to become an active useful person again.

Etiology

It is difficult to deal with a disease empirically. It is understandable, then, why primary

interest should center on laboratory and clinical research to elucidate the etiological and pathogenic mechanisms of the chronic diseases. We have only to look at the tremendous increase in the amount of money that has been made available for medical research in recent years, much of which is directed toward study of the etiology and pathogenics of the chronic diseases, to realize the urgency felt for knowledge to combat the ever-increasing burden of disability and death for which these diseases are responsible. It is estimated that in 1952 the Nation spent an estimated \$180 million for medical research: 42 percent came from government sources; 33 percent, from industry; 14 percent, from private philanthropy; and 11 percent, from hospitals and medical schools. The total amount is a tenfold increase over the expenditures for medical research of a decade before (2). In 1952, the Public Health Service administered \$18 million of grant funds to support medical research in addition to the funds for its own growing research program. The recent opening of the Clinical Center of the National Institutes of Health is a big step forward in furthering the research effort toward solving the problem of chronic disease development.

Almost every scientific discipline of the biological and natural sciences is represented somewhere on the research team attacking the array of morbid processes included in the chronic diseases; and research interest ranges from a study of the simplest biological systems to the response of whole organisms to experimental conditions. The volume of research findings is tremendous and is not easily synthesized into a total picture. However, there can be little doubt that the picture can be completed and the etiology and pathogenesis of the chronic diseases understood. From the public health vantage point, these research developments are to be viewed with keen interest and hope that better means of anticipating, diagnosing, and treating the chronic diseases will evolve.

Despite the momentum that chronic disease research is gathering, there is still the feeling that insufficient emphasis is being directed toward certain approaches to the study of the occurrence of chronic disease (3, 4). This stems partly from a lack of personnel with disciplinary training oriented to the chronic

as a tie-in or bonus feature of some other medical service; and (b) screening the population at risk periodically, the frequency to be determined from knowledge of the usual period between the time the screening procedure can first indicate presence of the disease and the time the disease will become manifest.

One important question is, How frequently should a screening procedure be repeated? Initial multiphasic screening of a population largely deals with prevalence of undiagnosed disease. Prevalence is the product of incidence times duration. If one disease has one-fifth the incidence of a second disease in a given population, but the former existed 5 years on the average asymptotically and the latter, 1 year, the findings in terms of numbers of cases of the two diseases in an initial screening will be the same. However, annual repetition of the screening would produce only one-fifth the number of new cases of the first disease, whereas the second disease would continue to be found in the same numbers. Perhaps repetitive screening for the first disease could effectively and economically be done on a 3- to 5-year cycle. The second disease is committed to annual screening.

One means of evaluating the accomplishments of multiphasic screening would be to compare the course of the cases of a disease so identified with the course of the same disease when first recognized symptomatically. Here we may be misled. Many diseases show a range of rates of progression. The slower-developing and more benign forms of the disease accumulate disproportionately among the undiagnosed, asymptomatic, cases of prevalent disease. Under these circumstances the prognosis for the prevalent cases as a group is more favorable than the prognosis for the incident cases.

Cancer is a disease for which more is at stake in earlier diagnosis perhaps than in any other of the so-called chronic diseases. Among the diseases usually grouped in the chronic disease category, symptomatic cancer is one of the more acute. It is primarily a killer, having the dubious distinction of ranking second in this capacity. Cancer is not found among the chronic diseases listed as responsible for the greatest amount of disability, either in terms of individual cases or collectively for all cases of specific diseases.

Since clinically recognizable cancer, that is, gross tumors that are obvious to direct or X-ray visualization, is such an acute disease, we have a narrow margin of time within which to accomplish asymptomatic diagnosis as a substitute for symptomatic diagnosis. Furthermore, we are forced to search for individual tumor masses at all the sites where they frequently occur because there is no established general pathophysiological change yet discovered associated with the development of cancer that is qualitatively or quantitatively sufficiently unique to serve as a general test procedure.

The cure rate for lung cancer, which has increased so remarkably in recent decades, is negligible when the disease has become symptomatic. Lung tumor masses can be identified in chest X-ray films before symptoms occur. Is this an effective and practical screening procedure for cancer of the lung? The lung cancer results of the Los Angeles mass X-ray survey suggest that X-ray screening can identify cases somewhere in the range of 9 months to a year prior to symptomatic diagnosis. Is this enough earlier to influence prognosis? There is some evidence from the Los Angeles data that it is (10), although the improvement still leaves much to be desired. Is the amount of improvement in prognosis real or are the results biased by an undue proportion of slower-growing tumors that can be expected among prevalent cases, as commented on earlier? Other sources of bias are likely in a survey of this type, and the results therefore cannot be regarded as definite. If it is felt that periodic X-ray chest examinations at 6-month intervals has real promise as a means of bettering the prognosis of lung cancer, it is worth a thorough, properly designed study of repetitive examinations in the same population.

The best example of a more hopeful aspect of discovering asymptomatic cancer is the use of exfoliative cytology for cancer of the cervix uteri. Contrary to what was said earlier regarding clinically recognizable cancer (visible gross lesions), the study of cervical cancer with cytology, whereby microscopic lesions without gross abnormality can be identified, suggests that cancer may be a very chronic disease, with the clinical stage as usually recognized being the explosive and lethal phase. The evidence

questionnaires became of necessity the method for collecting data. Union organizations seemed to offer the best means of gaining access to the occupational groups to be studied. The union organizations have proved to be very cooperative and the percentage of mailed questionnaires completed and returned has ranged between 85 and 90 percent, a most gratifying response. It is expected that the more than 25,000 workers that have entered the study will be increased three- or fourfold before the study populations are closed.

A few years ago a long-term study of heart disease was undertaken in Framingham, Mass., in which some 5,000 individuals were examined. These individuals will be followed over the next several years to determine the factors associated with the occurrence of heart disease. A study of coronary heart disease among London double-deck bus operators showed that conductors had fewer and milder cases of the disease than did drivers (7). It was hypothesized that the greater physical activity demanded of conductors in their work might be responsible for this finding. This explanation was supported by similar differences found for physically active and sedentary workers among postal workers and civil servants.

From these illustrations, it should be clear that the epidemiological method can make significant and worthwhile contributions to the understanding of the occurrence of chronic disease. Perhaps the time has come for public health workers to take a more active part in contributing what can be learned from population studies to these problems that are destined to absorb most of our interest and efforts in the near future.

Incipient Stage and Case Finding

It is generally agreed that diseases are more effectively treated if they are recognized in their early stages. This is particularly true for the chronic diseases where progressive and more or less permanent damage is a prominent feature of the pathological processes. In cancer control, the whole program is based on the concept of early recognition and treatment since success or failure is clearly centered on the time when metastasis occurs.

The problems connected with recognition of

the incipient stage of chronic disease are twofold: What techniques do we have for their recognition? How do we use them effectively? These two questions are intimately related to each other. A procedure that is technically difficult, time consuming, and expensive is hardly adaptable to examining the general population for unsuspected disease, for example, conventional gastrointestinal series for X-ray examination of the alimentary canal for possible cancer. On the other hand, procedures that are technically suitable for general application but lack sensitivity, specificity, or both will fail from lack of efficiency. An example would be a cancer test based on quantitative changes in the normal serum proteins that occur with this disease, or these diseases, as some prefer.

Dissatisfaction with the number of cases of symptomatic tuberculosis that were coming to diagnosis in the advanced stages led to technological development of miniature X-ray films and successful mass application of the new technique to screening the general population for cases of minimal, asymptomatic tuberculosis. Similar applications have been made of syphilis serology. Cancer detection centers were an outgrowth of this concept. It was natural to extend the concept to multiphasic screening, that is, combining screening procedures to look for a number of diseases simultaneously. So far, attempts to apply this method of identifying incipient and asymptomatic diseases have been sporadic and isolated. Reactions to these attempts have varied. They have been condemned as poor medicine and bad public health (8). However, multiple screening is considered to have a place if it can be meshed with the normal flow of patients through medical channels, such as physicians' offices, outpatient departments, hospitals, and industrial medical examinations (9).

The basic question, however, seems to me to be whether screening procedures can be the means for bringing the diseases in question under medical management in an incipient or asymptomatic stage rather than in the symptomatic stage when diagnosis is usually made. This implies two things: (a) making the procedures available to the general population, or to those segments at major risk from the diseases being sought, as a direct service and not

research is certain to come an understanding of the detailed mechanism of many of the chronic diseases and, from this understanding, the development of many specific and potent therapeutic agents will follow.

This is a phase of chronic disease research which is not directly related to public health responsibility. Interest has been extended to an evaluation of the efficacy of therapy, such as the use of tumor registries in the cancer field. Therapeutic advances can have considerable effect on the community load of the disabled and incapacitated chronically ill which is a direct interest and responsibility of public health.

The Chronically Ill Population

The philosophy of chronic disease control is to prevent and to mitigate the burden of chronic disease that is now prematurely disabling and incapacitating large numbers of our population. It has been estimated that 4,000,000 persons in the United States are continually victimized by these conditions, three-fourths of them under 65 years of age (12). Even with postponement of death through control of disease there will always be a need for community services for those reaching the incapacity of old age and terminal illness (13).

Public Health Responsibility

How can public health assay its responsibilities for the chronic diseases without defining the problem in terms of numerical size; relative importance of the various diseases and injuries in terms of incidence and prevalence; nature of the incapacities; type of care being given, by whom, and in what degree of adequacy; unmet needs and who can best provide them; availability of community services and facilities; possibilities for rehabilitation and the availability of this service; and a host of other questions that require answering as the chronic disease problem is dissected and analyzed? A number of morbidity studies are going on now—in New Jersey, Baltimore, and the State of California—to answer many of these questions. In other studies, such as that of the Community Studies, Inc., of Kansas City, Mo., the possibilities and cost of rehabilitating the handicapped and chronically ill are being determined.

The generalizations that can be drawn from these studies will be helpful in gaining insight and in providing guidelines for understanding and planning programs to aid and rehabilitate the chronically ill. Each community, however, will have to examine its own problem, do the best it can with what it has, and attempt to discover and rectify its weaknesses. Such community introspection perhaps cannot be graced with the designation of research, but here is where the problem and the solution lie for the care and rehabilitation of our chronically ill.

Summary and Conclusions

1. The chronology of chronic disease is considered from the standpoint of public health interest and responsibility.
2. There has been greatly increased financial support for research directed toward the chronic diseases in recent years, with major emphasis on laboratory and clinical research.
3. The epidemiological method, primarily a tool of public health, has been relatively neglected as a research approach to studying the chronic diseases.
4. Case-finding methods have been inadequately evaluated. A number of questions are posed that must be answered before these methods can be used intelligently and with predictable results.
5. Laboratory and clinical research will eventually elucidate the mechanisms of many of the chronic diseases. Some of these findings will be found adaptable for practical application as preventive measures. These findings should also be scrutinized for adaptation as more discriminatory case finding methods.
6. Advances in therapeutic management give promise of better control of the chronic diseases from the standpoint of stopping or delaying progression before disability and incapacity result.
7. As of now, however, there is a sizable and growing burden of chronic illness and disability among our people which will always be with us in some degree. Public health has the responsibility of studying the problem and contributing its skills to the prevention and control of these diseases, and the support and rehabilitation of those affected.

indicates that there is a preinvasive stage that lasts for several years. Periodic searching for evidence of this lesion, which would seem to be almost certainly curable, may be successfully accomplished at 2-, 3-, or 4-year intervals. A study now in progress in Memphis, Tenn. (11), is using exfoliative cytology to determine whether cervical cancer can be made a relatively nonlethal disease when the general population of females is periodically screened by this procedure. Unfortunately, the cytological method is not well adapted to screening for other sites of cancer because of the technical difficulties of obtaining specimens.

The more important questions relative to the substitution of asymptomatic diagnosis for symptomatic diagnosis of the chronic diseases are:

1. What procedures do we have that are technically suitable for mass application?

2. How efficient are these procedures in terms of sensitivity and specificity when used in the asymptomatic general population?

3. What is the pattern of the specific diseases that are being sought in terms of incidence, prevalence, age, and sex selection, and so on?

4. How much earlier, on the average, can the screening procedure pick up the specific disease than it is usually diagnosed as a result of symptoms?

5. As a corollary to this, what is the cyclic frequency for most practical and efficient use of the screening procedure?

6. What is the advantage in prognosis for cases of the disease identified by the screening procedure as compared to those progressing to symptomatic diagnosis?

If intelligent and efficient use is to be made of the concept of multiple screening, such questions as these must be answered no matter how the method is to be applied. If the idea is to be effective in improving the total chronic disease picture, it must be promoted in some organized plan in making it continuously available for any population group. Public health has traditionally taken the leadership in case-finding methods and has most to gain from answering questions such as those proposed. This knowledge is needed if we expect to do more than enumerate for demonstration purposes the number of unattended and undiagnosed dis-

eases and defects that are prevalent in any population in which symptoms are the usual basis for seeking medical attention.

Symptomatic Clinical Disease

The symptomatic clinical stage is the stage of disease for skilled medical management. And the emphasis here is on treatment. The therapeutic advances made and being made are spectacular and become matters of public knowledge almost as rapidly as they appear. The antibiotics have become so well established and are available in such variety to meet almost every special purpose for combating infectious agents, that we accept them as part of our medical heritage. The sulfa drugs, which were the marvel of their day, have already passed into that heritage. Current developments in the manipulation of hormones to influence the course of certain chronic diseases, using the concept of metabolic antagonists in cancer chemotherapy, more effective antihypertensive drugs, and so on, are examples of important progress in therapy for the chronic diseases.

Much of the fundamental research that is being so extensively carried on is directed to an understanding of the basic chemical processes of metabolism in the normal state, in disease, and under the influence of therapeutic agents. Interest includes the cellular components identified with metabolic functions; hormonal effects on cellular metabolism and tissue function; the in vivo fate of therapeutic agents in terms of chemical alteration of the agent, specific action in chemical and functional terms, storage, and excretion; and the chemical nature and physical-chemical state of nutritional elements during blood transport, in tissue fluids, and body storage. The development and perfection of research tools such as radioactive isotopes, electron and phase microscopy, electrophoresis, paper chromatography, and high-speed centrifugation have done much to make this detailed and exacting research possible. Many of the advances in specific means of controlling infection, in understanding of the physiological economy of the body, and in improved anesthesia have made possible the extension of surgical procedures in the cardiovascular, cancer, and other fields.

Out of this extensive medical and biological

As More People Live Longer

The eighth annual conference on aging, held during the week of June 27, 1955, at the University of Michigan, Ann Arbor, had an official registration of 804. Representatives of 30 States, the District of Columbia, 3 Canadian Provinces, England, and Sweden attended the general sessions and the various workshops.

Sponsors of the conference were the University; the Department of Health, Education, and Welfare; the Department of Labor; the Civil Service Commission; the Housing and Home Finance Agency; the Council of State Governments; United Auto Workers, Congress of Industrial Organizations; Michigan State Medical Society; and the Michigan State Departments of Employment Security, Agriculture, Health, Public Instruction, Mental Health, and Social Welfare.

The chairman of the conference, Dr. Wilma Donahue, who is chairman of the division of gerontology, Institute for Human Adjustment, University of Michigan, reports that one outgrowth of the conference was the formulation of emerging concepts by which the problems associated with aging might be approached. These observations and principles are presented below in the form of a list of tentative conclusions reported by the conference research seminar.

- The proportion of the people in our society who are old is probably going to remain at about the present level to the end of this century. The number of older persons will increase along with the numbers in all other age groups.
- As with other segments of the population, older people can expect more of the better things of life, more leisure and time for creative pursuits as our national productive capacity expands in line with the extension of automation.
- As a result of our added years, all of us will spend more years in the work force, but these years will constitute a smaller proportion of our lives. There will be further decline in work force participation after age 65.

- There is no immediate prospect of a dramatic rise in the total length of life. There will not be a great increase in the life span, but, as a result of medical progress, more of us will live into the older years.

- By employing the emerging concept of treatment of the whole person as opposed to a focus on a particular disease entity, we are achieving spectacular results in restoring the individual to self-function and to a useful place in society. Moreover, treatment of the total person through utilization of the team approach, and the coordinated services of the community can reduce the period of hospitalization from one-third to one-half.

- It is increasingly recognized that the problems of the later years have their onset in the middle years. Therefore, there is need for increased focus on prevention and planning in the fields of health, income maintenance, use of leisure time, education, and living arrangements.

- We may expect continuing pressure on the part of older workers to remain in the labor force until it is possible to guarantee income security and other meaningful roles.

- The need for income maintenance will continue to be a primary concern, and, if present trends continue, we might expect this income to be derived from deferred earnings in the form of social security, private pensions and related benefits, and to a limited extent from personal savings. Also, the provision of more services, such as adult education, recreation, and preventive health services by the community, will contribute to the improvement of the economic status of older people.

- The kinship and household pattern of three-generation families has all but given way to the separate family unit composed of man and wife or of man, wife, and immature children. To a very large extent, the two generations of grandparents and parents are mutually independent and prefer to follow their peer group relationships.

- It might be expected that increasingly inter-

Education for the Professions

Office of Education Publication. By Lloyd E. Blanch. 1955. 317 pages. Paper, \$1.75; buckram, \$2.75.

This detailed and extensive sourcebook on education for the leading professions in the United States describes these professions and reports on their development and current status of education. It indicates some of the major problems in professional education, lists schools offering professional curriculums, and presents additional reference information.

Twelve chapters are devoted to the health professions: chiropody, dentistry, hospital administration, medicine, nursing, occupational therapy, optometry, osteopathy, pharmacy, physical therapy, public health, and veterinary medicine. Other fields

include accountancy, agriculture, architecture, business administration, engineering, forestry, home economics, journalism, law, library service, music, public administration, social work, teaching, and theology. There are also chapters covering the education of officers in the Army, Navy, Marine Corps, Air Force, Coast Guard, and Merchant Marine.

Outpatient Psychiatric Clinics, 1954

Public Health Service Publication No. 428. 1955. 44 pages. 35 cents.

The first in a series of publications compiled in connection with the new national mental health clinic statistics program, this listing is intended to serve as an interim reference on existing clinics. It is for

the use of professional personnel in community agencies throughout the country.

Name and address of each facility meeting a uniform definition of an outpatient psychiatric clinic are listed by State and location. Appendix A gives headquarters of clinic outlets by State and appendix B, agencies designated as State and Territorial mental health authorities.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

Survival of Enteric Organisms in Sea Water

By ARNOLD E. GREENBERG, S.M.

THE increased use of ocean beaches and tidal areas for recreational activities and commercial shellfishing, coupled with the increased volume of sewage being discharged into the ocean and the heightened interest in general pollution control, has served to make the problem of salt water contamination acute. This is especially true in a coastal area such as California, which is experiencing a tremendous population growth.

Although the problem of controlling this contamination is basically an engineering one, a public health laboratory can be of real assistance in compiling and evaluating available information on the occurrence and survival of enteric organisms in sea water. Consequently, a review of the literature is reported by the division of laboratories of the California State Department of Public Health.

The reader's attention is called to two references which are of particular interest and value. These are Zobell's *Marine Microbiology* (1), a book which deals with the entire problem of micro-organisms in the sea, and Moore's com-

prehensive review on the contamination of ocean beaches (2).

Some of the Early References

For more than half a century it has been known that sea water can be significantly contaminated by human wastes and that this contaminated water may be a factor in the transmission of enteric diseases either through the direct use of the water or indirectly through shellfish which have been exposed to it. The first study on this subject was reported in 1885 by Nicati and Rietsch (3), who were able to recover the cholera vibrio from the water of the old harbor at Marseilles during a cholera epidemic. In a series of laboratory experiments they showed that the survival of *Vibrio comma* varied in different waters. For example, the organism could be recovered from sterilized harbor water 81 days after inoculation, while in sterilized water from the open sea the survival time was reduced to 64 days. In polluted fresh water, however, the organism could not be recovered after 32 days.

In studying the Bay of Naples, de Giaksa (4) determined that enteric bacteria die off rapidly in the sea. In heat-sterilized sea water the typhoid bacillus and the cholera vibrio survived 25 and 36 days, respectively, while in raw sea water they persisted for only 9 and 4 days. He found that the total number of bacteria markedly affected the survival of the cholera bacillus; there was an inverse relationship between total bacterial count and survival time. He isolated a number of strains of marine bac-

Mr. Greenberg was appointed chief, sanitation laboratory, division of laboratories, California State Department of Public Health in February 1955. Formerly research microbiologist, University of California Sanitary Engineering Research Laboratory, Mr. Greenberg is also author of papers on biological stabilization of industrial wastes, biological treatment of radioactive wastes, and reclamation of sewage water.

generational relationships will become voluntary in nature as opposed to socially defined, legal, or moral obligations. These relationships will instead be based on affection, congeniality, and mutual interests.

- There is much evidence that leisure will occupy a greater proportion of our lives. This has clear implications for community provision of additional facilities and services for leisure-time pursuits for all generations.

- There exists in many communities a need for the coordination of medical and social services to reduce the problems of institutional medical care and the costs of such care of the old.

- Older persons can do much toward minimizing their own personal adjustment problems by contributing their services where they reside in cooperation and in participation with all other age groups in helping to meet the community needs.

• • •

A brief summary of the conference appears in the September 1955 issue of Geriatrics. Some of the other materials presented at the conference will be published by the University of Michigan Press during the spring of 1956 in a book entitled "Aging's New Frontiers."

Federal Surplus Property

Federal surplus property costing \$56,667,227 was distributed to States for public health and educational purposes during July, August, and September, 1955, by the Department of Health, Education, and Welfare.

Under the Federal Property and Administrative Services Act of 1949, the Department channels surplus property to State and local government agencies and to

nonprofit institutions, which are exempt from Federal taxes, in the fields of public health and education.

Property transferred includes school and hospital building sites, buildings suitable for students or faculty, motor vehicles, furniture, tools, laboratory equipment, and school and office supplies. Most of the surplus property comes from the Department of Defense.

Disposition of Federal personal and real surplus property (acquisition cost), July 1–Sept. 30, 1955

sults of such experiments may, therefore, have little sanitary significance.

Zobell (18) avoided this objection by using sewage bacteria directly, without cultivating them in the laboratory. Comparing the survival of these bacteria in sea water and sewage-diluted sea water, he found that a concentration of 5 to 10 percent of sea water favored the survival of bacteria, whereas higher concentrations produced rapid killing. In 75 percent sea water the bacterial count was reduced to 39 percent of the original in 2 hours.

The general problems of the discharge of sewage into the Atlantic and Pacific Oceans have been discussed, respectively, by Weston (19) and Warren and Rawn (20). They indicated that enteric bacteria occur in significant numbers only in such places as tidal zones, harbors, and bays.

Zobell (21) confirmed these observations by finding coliform bacteria absent in 961 samples taken from the open sea but regularly present in samples from bays and estuaries. He attributed the die-off of coliform bacteria to the paucity of organic matter and the activity of predatory organisms, believing sea water itself, however, to be slightly toxic for *E. coli*.

Carpenter, Setter, and Weinberg (22) observed that sea water has considerable disinfecting properties on fresh sewage organisms. In their experiments an average of 80 percent of the organisms died in 30 minutes.

The Massachusetts Department of Public Health (23) and Weston and Edwards (24) have reported the results of an investigation made at the Lawrence Experiment Station. After mixing sewage with sea and tap water, at rates of 0.5, 1.0, and 1.5 percent, the total number of bacteria and number of coliforms were followed for 4 days. Both in the raw sewage and the sewage-tap water mixtures the bacterial count decreased slowly, but in the sewage-sea water mixture the decrease was very rapid. No coliforms survived beyond 4 days in the latter mixture.

During the course of examining the Santa Monica beaches, the California Department of Public Health (25) showed that marked coliform reductions occurred in samples of contaminated sea water held for 24 hours. At refrigerator temperatures, from 5 to 20 percent

of the coliforms survived. At room temperature, however, only 1.0 to 2.5 percent of the original number of coliform bacteria could be recovered after 24 hours.

Stryszak (26), working in Poland with several *Salmonella* species, found that the waters of the Gulf of Gdansk (Danzig) produced a rapid kill when the temperature was between 5.5° and 18.5° C. Lower temperatures resulted in reduced kills.

Ketchum and his colleagues (27), in the first of several papers from the Woods Hole Oceanographic Institute, concluded that coliform bacteria rapidly disappeared from normal sea water. This disappearance was more rapid than could be accounted for by such mechanical factors as dilution or sedimentation.

In a later paper from the Woods Hole laboratory (28), the bactericidal action of sea water was shown to be the most important factor in decreasing coliform counts. The total reduction was 99 percent.

Buck, Keefer, and Hatch (29) found that coliforms could persist in estuary water for longer than 200 days.

The North Sea has been examined by several investigators who recovered a number of pathogenic enteric bacteria (30). Buttiaux and Leurs (31), for example, found *Salmonella montevideo*. Their experimental work indicated that with 3 species of *Salmonella* there was more than 90 percent kill in spring water in 44 hours but that in sea water the number of survivors was greater.

As a result of studies similar to the ones mentioned, attention has turned to the reasons for the bactericidal effect of sea water and the quantitative determination of its importance. The explanations suggested by Waksman and Hotchkiss (32) for the low numbers of viable bacteria in water have been summarized as follows:

1. The presence in sea water of toxic substances which are destructive to bacteria under natural conditions.
2. The presence of bacteriophage in the water.
3. The adsorption of the bacteria by the sea bottom and their sedimentation.
4. The bactericidal effect of sunlight.
5. The consumption of the bacteria by protozoa and other small animal organisms.

teria which possessed definite antagonistic activity for the cholera bacillus and also for the nonenteric anthrax bacillus. De Giaksa concluded that water of the open sea could probably not be a means of spread of disease but that, in spite of the relatively rapid death rate in harbor water, such water might be infectious. He also indicated that fish and shellfish might be involved in disease transmission.

Fränkel (5), in a like manner, recovered cholera bacilli from the harbor at Duisberg, presumably after contamination of the water by the discharge from a ship on which cholera was present among the crew.

In connection with investigations on the contamination of shellfish and the possibilities of purifying them, a number of observers commented on the survival of enteric pathogens in sea water.

Conn (6) cited Burdoni, who showed that the typhoid bacillus would live in sea water for 14 days.

Foote (7) noted that, in raw brackish water with a salt content of 0.06 to 0.15 percent, the survival of typhoid organisms was a function of temperature, there being greater survival when the temperature was above freezing.

Reille (8) stated that, according to his experiments, sea water was favorable to the survival of typhoid bacteria.

Boyce and Herdman (9), on the other hand, claimed that typhoid bacilli will not flourish in clean sea water, and Klein (10) observed that sea water had a "powerful destructive action" on *Salmonella typhosa* but that survivors could be recovered even weeks after the collection of samples of heavily infected water.

Later, Winslow and Moxon (11), during a study of bathing beaches in New Haven Harbor, Conn., were able to recover large numbers of coliform bacteria. Although they did not discuss the factors which affected the coliform numbers, they did mention that tides and winds played a part in the distribution of bacteria. A combination of flood tide and onshore wind produced the least dispersion and the highest counts.

In a survey of sewage outfalls in Los Angeles, Knowlton (12) found that the coliform count decreased more rapidly than could be accounted for by dilution alone. After collecting samples

with high coliform counts at bathing beaches distant from the outfall, he concluded, "These conditions lead me to believe that *B. coli* contamination may be caused by bathing only."

Survival in Sea Water

It is obvious from these earlier references that an appreciation of the problem existed long before there were adequate means for studying it. Conflicting reports on the effect of sea water on enteric micro-organisms pointed up the need for much additional work. Although subsequent studies did not all agree in their results, they have shown conclusively that there are factors present in sea water which decrease the survival of enteric organisms.

Trawinski (13), from his observations of the survival of various enteric pathogens in sea water and in the water from sewage outfalls, found that several members of the typhoid group survived for shorter time periods in the outfall water than in water from the open sea.

Burke and Baird (14) reported that fresh water bacteria could survive equally well in fresh or salt water.

Kořínek (15), after attempting to grow a number of fresh water and soil bacteria in media made with sea water, concluded that, although the micro-organisms could grow quite well on a sea water medium, in nature they have only a latent development in the sea.

The cholera vibrio was observed by Kiri-bayashi and Aida (16) to survive, on the average, for only 10 days in the water of Keelung Port, Formosa, but in the laboratory it survived longer.

In a series of carefully conducted experiments Beard and Meadowcraft (17) studied the survival of pure cultures of *S. typhosa* and *Escherichia coli*. The organisms were put into cells made essentially of a semipermeable membrane, and the cells were suspended in San Francisco Bay. After 35 days no typhoid bacilli and few coliforms could be recovered from the cells.

Experiments using laboratory cultures of the test micro-organisms are of questionable value since it has been shown that laboratory-propagated strains have a greater resistance than naturally occurring bacteria (2, 18). The re-

icity factor is insufficient to account for the observed death rates or survival times.

Presence of Other Toxic Substances

The presence of other toxic substances has been stressed in recent years.

Zobell and Feltham (36) were among the first to make specific mention of the possible presence of such substances.

Waksman and Carey (39) spoke of "certain controlling factors" injurious to free bacterial development but made no attempt to characterize them.

Careful experimental work is described in an article by Zobell already cited (18). The test bacteria were submerged in the sea within Coors porous porcelain filter tubes impregnated with collodion. This semipermeable membrane permitted the passage of chemical substances from the sea water into the bacterial suspension but did not permit bacterial passage into the sea water. It was found that the death rate of sewage bacteria suspended in autoclaved sea water or sea water which had been passed through a Berkefeld filter was lower than that of bacteria in raw sea water.

A similar observation was made by Kiribayashi and Aida (16), who noted that cholera vibrios survived longer in boiled and sterilized sea water than in the untreated liquid.

Beard and Meadowcraft (17) concluded that the death rate of *E. coli* and *S. typhosa* was higher in unfiltered sea water than in filtered sea water.

Krassilnikov (40) found that a bactericidal factor also was present in the waters of the Black Sea. This factor was active against *E. coli* and was removed by passage of the water through a Seitz filter as well as by boiling or by heat sterilization, and its effect was overcome by the addition of organic matter. At a concentration of 0.1 percent of peptone it was completely absent.

The data of Ketchum, Carey, and Briggs (27) showed that there was a bactericidal principle in sea water which could be destroyed almost completely by autoclaving but only partially by boiling. This factor was not related in any simple way to the chemical composition of sea water. They suggested that the factor

may be an antibiotic substance or an autolytic or degenerative product of the coliforms themselves.

In a continuation of this work, Vaccaro, Briggs, Carey, and Ketchum (41) determined that sea water treated by boiling, autoclaving, pasteurizing, and chlorinating had reduced bactericidal activity. The addition of organic matter also produced reduced activity although not as much as did sterilizing the sea water.

As part of an investigation of the viability of sewage bacteria with respect to shellfish purification, Sherwood (42) found that growth generally occurred in autoclaved sea water but not in raw sea water. By passing the treated water through sterile porcelain filters the effect of autoclaving was removed. Treated sea water which supported the growth of *E. coli* would not permit the persistence of heavy infections of *S. typhosa* or *Salmonella paratyphi* B.

De Balsac, Bertozzi, and Gaudin (43) observed that the bactericidal activity of sea water was independent of salinity, decreased with sample age until it disappeared after 8 to 10 days, was thermolabile, and persisted after passage of the water through a Chamberland filter.

It has clearly thus been established that sea water contains a potent toxic factor which is thermolabile. The isolation and identification of this factor has as yet to be accomplished.

Presence of Bacteriophage

Numerous investigators have confirmed the presence in sewage of bacteriophages active against enteric bacteria.

As early as 1896 Hankin, cited by d'Herelle (44), noted the effects of bacteriophages.

Arloing, Sempé, and Chavanne (45), as a result of their experiences, believed that the disappearance of fresh water bacteria in the sea was due to the action of specific phages.

Guélin (46), who is one of the foremost students of bacteriophage and its sanitary significance in water, found that bacteriophages active against the coli-typhoid dysentery group were present in the port of Roscoff (France). The number of phages varied directly with the degree of sewage contamination. However, no conclusions were drawn as to the role these

6. The possible presence in the sea of inactive bacteria which are capable of developing only under more favorable conditions of temperature, aeration, and food supply.

7. The lack of sufficient nutriment in the water.

8. The antagonistic relations of other micro-organisms.

It will be convenient to discuss the more important of these categories separately.

Presence of Inorganic Salts

The most potentially toxic substances present in sea water, on the basis of concentration, are inorganic salts. The salinity of surface sea water is given by Zobell (1) as from 3.3 to 3.7 percent. Near river mouths and other areas of fresh water dilution, this concentration of salts may be appreciably reduced. In inland seas, it may be greater. The effect of high salt concentrations on fresh water or enteric bacteria may be due to differences in osmotic pressure or to the presence of specific inhibitory salt concentrations.

As early as 1890, de Freytag (33) investigated the effect of concentrated solutions of sodium chloride on a variety of bacteria. Unfortunately, he did not mention the salt concentrations used, nor did he compare the survival times with any fresh water controls. He found that, although the typhoid bacillus survived for longer than 5 months, the cholera bacillus died out within 6 to 8 hours.

After comparing the growth of several fresh water bacteria on media containing varying concentrations of sea water, Kořínek (15) concluded that the test organisms could grow quite well on a sea water medium. Furthermore, sea water exerted no marked autolytic effect.

Reporting on the extension of this work, Kořínek (34) noted that fresh water bacteria usually do not compete successfully in the sea with marine bacteria.

The survival of bacteria in an 0.85 percent saline solution and in distilled water was compared by Ballantyne (35), who showed that in either menstruum—in the absence of nutrients—micro-organisms, including *S. typhosa*, were able to survive up to 32 months.

Burke and Baird (14) assumed that the principal factor of difference in fresh water or salt water survival of bacteria was the concentration of sodium chloride. The results they obtained, however, did not support this assumption. Although no data are given in their report and the test micro-organisms are not identified, they claimed that fresh water bacteria survived in sea water nearly as long as in tap water. The length of survival depended on both temperature and the presence of organic matter. Nutrient broths prepared with 2 to 4 times the concentration of salt present in sea water permitted the extended survival of fresh water bacteria. Sea salts other than sodium chloride did not affect viability. Thus, in general, these authors support the viewpoint that inorganic salts affect slightly, if at all, the survival of nonindigenous bacteria in the sea.

Zobell and Feltham (36) in a discussion of marine bacteria mentioned that "the toxicity of sea water for nonmarine bacteria is due not only to its high salt concentration, but to some other factor as well," indicating that they considered the salts to exert some toxic effect.

In a later work Zobell (18) studied the survival of sewage bacteria in artificial and natural sea waters as well as in sodium chloride solutions. He showed that the death rates in the synthetic solutions were markedly different from those in the chemically similar sea water.

The Great Salt Lake in Utah obviously does not contain sea water, but its salt concentration of more than 25 percent makes it interesting in this connection.

Zobell and his associates, Anderson and Smith (37), in an attempt to grow *E. coli* on a lactose medium made with lake water, were unable to observe any gas production or to recover viable coliforms. They stated that the lake water would kill over 95 percent of the sewage bacteria in 1 minute.

Conflicting results, however, were obtained by Fraser and Argall (38), who claimed that *E. coli* was not rapidly killed and that the length of the survival time increased as the temperature decreased.

In summary, it would appear that the usual concentration of salts present in sea water may exert some bactericidal action, but that this tox-

perature; however, at 6° C. approximately 50 percent survived a 24-hour exposure.

Ballantyne (35), in his work with physiological saline, found that *S. typhosa* also survived longer at low temperatures.

In spite of the conflicting reports on the effect of temperature on bacteria in sea water, there is no reason to believe that its effect will be materially different than it is in fresh water or any other aqueous system. Unfortunately, such information is equally conflicting, so that, in any given environment at ordinary temperatures, it is impossible to predict the effect of temperature changes other than to say that the tendency for increased survival is greater at lower temperatures.

Aeration and Food Supply

The dissolved oxygen concentration, which is a function of temperature, pressure, salinity, and biological activity, may be used to measure the degree of water aeration.

The only information available on the relationship between micro-organisms and oxygen content in natural sea water is the observation by Buttiaux and Leurs (31) that oxygenation of sea water did not affect the survival of *Salmonella typhimurium*.

Waksman and Carey (53) showed clearly that in stored sea water the oxygen content affected bacterial multiplication.

Zobell and Anderson (54) attributed this increase in numbers to the effect on the solid surface of the container, rather than to oxygen tension.

Under most circumstances survival, and more especially reproduction, of bacteria is associated with available nutrient materials.

Russell (47) found that multiplication of bacteria was quite marked in marine muds which are relatively rich in organic matter. He did not comment on the survival of bacteria in waters containing different concentrations of organic matter.

Burke and Baird (14) believed that the presence of organic matter in sea water would increase the survival time of nonmarine bacteria.

Waksman and Carey (39), in their investigation of the decomposition of organic matter in

the sea, concluded that sea water contains enough organic substances in true solution to support an extensive population of bacteria. They did not indicate whether they believed that enteric bacteria or fresh water bacteria could thrive in such an environment.

In another study, Waksman and Vartiomaara (49) showed again that rapid and considerable increases in bacterial numbers took place following adsorption of parent bacteria on marine muds. The neutralizing effect of organic matter on the bactericidal principle in sea water has already been mentioned (40, 41).

Steininger (30) found that at ebb tide the concentration of protein in the standing water of tidal pools was sufficient to provide favorable conditions for the multiplication of *S. paratyphi* B.

An unsigned editorial in the *American Journal of Public Health* (55) commented on the destruction of the bactericidal principle in sea water by autoclaving but not by boiling (27) and suggested that instead of being an antibiotic substance this principle was, in fact, not a toxicity but a starvation problem. Thus, chemical compounds present, but unavailable as nutrients to coliform bacteria, were decomposed by the elevated temperature of the autoclave (but not by boiling) and produced products "which enable the coliform bacteria to maintain themselves more efficiently" (55).

It should not be concluded that under all circumstances the chance of survival or of reproduction of the enteric bacteria is improved by the presence of organic matter. In the event that there is sufficient organic matter present to support growth, a competition between enteric organisms and saprophytes indigenous to either the fresh water or marine habitat would follow. Generally, the enteric organisms would be unequal to the competition. If we consider that the total number of bacteria in the sea is a direct function of the concentration of organic matter, it follows that there will be more competitors of the enteric bacteria as more organic substances occur and that these other organisms, either directly or indirectly, will reduce the growth and survival of the fecal bacteria. This has been shown by de Giava (4) and Kořinek (34).

phages play in the destruction of enteric bacteria.

De Balsac and co-authors (43) believed that the bactericidal activity which they observed was not due to bacteriophages.

There are too few data available to be able to draw sound conclusions on the role played by bacteriophages in limiting the survival of enteric bacteria in sea water. The indications, however, are that the phages are not of the first order of importance.

Adsorption and Sedimentation

Russell (47) observed that the concentration of bacteria in the Gulf of Naples was highest in the bottom muds. Although he attributed this distribution to the growth and multiplication of indigenous bacteria, he showed that the mud could take up bacteria which derived from the mainland.

Rubentschik, Roisin, and Bieljansky (48) believed that the disappearance of coliforms introduced into the limans or salt lakes of the Odessa region, by drainage from sewage fields, was due primarily to the adsorption of the bacteria on muds. The adsorption capacity of ground sediments in the Chadjibey liman for *E. coli* was quite high. The shallowness of the lakes, particularly near the shore, and the tidal action were responsible for rapid mixing of sediments with the surface water. This in turn produced conditions favorable to adsorption of bacteria.

Waksman and Vartiomaara (49) also found that marine muds had marked adsorptive effects on bacteria. Sand, on the contrary, possessed slight adsorptive properties.

These results are in accord with accepted theories of the nature of soil. Clay and silt, which constitute a major portion of the mud, are electrically charged, and hence, are adsorptively active. Sand, however, not only has a larger particle size and, thus, has less relative surface area, but it is also electrically neutral.

According to the theory held by Dienert and Guillard (50), sea water is neither antiseptic nor inimical to *E. coli*, but sewage discharged into the sea is purified by sedimentation as well as through the activity of predatory organisms.

In a careful study Weiss (51) determined the

adsorptive effect of silt taken from rivers and estuaries. He showed that the degree of adsorption was a function of particle size and the physicochemical nature of the particle. The turbidity found in many natural waters was high enough to yield measurable adsorption of *E. coli*. The end result of this adsorption of bacteria by relatively heavy particles is an increase in the rate of bacterial removal by sedimentation. However, sea water generally reduced the adsorptive capacity of silts, and, furthermore, desorption may have taken place.

It may be concluded that adsorption and sedimentation of enteric organisms do occur, but they will be affected by the nature of the bottom deposits, the rate of desorption, and the rate of water movement, that is, the factors adversely affecting sedimentation. Adsorption and sedimentation do not, in themselves, affect the survival of bacteria but merely tend to remove the organisms from suspension and concentrate them in bottom deposits where they may continue an active existence.

Sunlight and Temperature

Although a considerable amount of information on the bactericidal effects of sunlight has been accumulated, there are few references dealing with this effect in sea water.

Gaarder and Spärck (52) have studied this phenomenon and considered it to play a significant part in the destruction of organisms in the sea. In all likelihood it is a contributing factor in bacterial destruction but of secondary importance only.

The effect of temperature has been mentioned in some of the references already cited.

Burke and Baird (14) found that fresh water bacteria inoculated into sea water survived longer at 20° to 22° C. than at 7° to 12° C.

Waksman and Carey (53), in studying the effect of storage of sea water on bacterial multiplication, noted that temperature had a marked effect on changes in numbers of bacteria. As the temperature increased to an optimum, the rate of multiplication also increased.

Fraser and Argall (38) reported that in waters of the Great Salt Lake few *E. coli* survived for longer than 8 hours at summer tem-

Antibiotics and Animal Predators

De Giaksa (4) was the first to report the existence in the sea of bacteria antagonistic to *V. comma*. After growing these unidentified organisms in mixed culture with *V. comma*, he was unable to produce an experimental infection in animals. Pure cultures of the vibrio were, on the other hand, quite infectious.

Kiribayashi and Aida (16) assumed that the toxic principle in sea water was associated with the presence of saprophytic micro-organisms.

Zobell (18) and Waksman and Hotchkiss (32) observed the bactericidal action of sea water. Waksman and Hotchkiss did not attribute this action to a chemical factor. They found that the toxic agent did not interfere with the decomposition of organic matter as measured by oxygen uptake. Since the reduction in the number of bacteria was not accompanied by a decrease in oxygen consumption, they concluded that other living organisms, namely protozoa and other nannoplankton, were responsible for the reduction.

This point of view was held also by Stryszak (26), who believed that the effect of low temperatures on the increased survival of *Salmonella enteritidis*, *S. typhosa*, and *S. paratyphi B* was due to the thermal inactivation of predatory protozoa rather than to any more direct temperature effect. Similarly, when the concentration of organic matter increased, the population of saprophytes and animal predators did the same. From this effect Stryszak inferred that the predators were most important in the elimination of enteric pathogens from the sea.

Rosenfeld and Zobell (56), in comparing the bactericidal properties of sea water and cultures of antagonistic marine bacteria, found that both the sea water and the cultures suffered losses in activity after filtration through bacteria-proof filters and that both were, on the whole, active against the same organisms. Most of the antibiotic-producing bacteria belonged to the genera *Bacillus* and *Micrococcus*. Although antibiotic activity against *Proteus* sp., *S. typhimurium*, and *Shigella paradysenteriae* was not shown, activity against several gram-positive bacteria was demonstrated. It was concluded that the bactericidal activity of sea water "may be at least partially due to an

autochthonous flora of antibiotic-producing organisms" (56).

Vaccaro and co-workers (41) believed that a normal population of marine bacteria was a necessary condition for bactericidal activity of sea water. They said:

"... the preponderance of evidence thus points toward an antibiotic action, but it can not be stated categorically that all other possibilities have been excluded. The character of the activity is such that it suggests that the bactericidal substance is present in very small concentration."

Ketchum, Ayers, and Vaccaro (28) completed a study of a tidal estuary with a mathematical analysis of the factors contributing to the decrease in coliform counts and showed that bactericidal action was considerably more significant than either dilution or predation. Unevaluated factors were from 3 to 7 times as effective as dilution but were not as effective as bactericidal action in reducing counts.

From the foregoing it may be concluded that the single most important factor in reducing the number of enteric bacteria in sea water is a biological one and most likely is the result of the production of antibiotic substances by marine bacteria.

Summary and Conclusions

From a review of the literature on the survival of enteric organisms in sea water, it is apparent that these organisms can create a health hazard in estuaries, bays, and especially beaches. The rate of disappearance of the fecal bacteria is greater than that which would be expected from dilution alone. A number of factors are implicated. These include the production by marine bacteria of unidentified, heat-labile antibiotic substances; and adsorption and sedimentation, predation, and competition for the limited food supply. The net result is a partial or complete disinfection or self-purification of sea water. Nevertheless, this bacterial destruction should not be relied on as the sole protection offered to users of sea water.

The methods and plan of a pilot study to obtain definitive data on the effects of air pollution on the health of selected cardiac and respiratory patients in their homes.

Measuring Reactions to Air Pollution

By JOHN J. PHAIR, M.D., and MAURICE L. THOMSON, M.B., Ph.D

THE nature and extent of the effect of air-borne contaminants upon man's health are still matters for speculation. Most of the available and very scanty data have been gathered from three sources—the broad field of industrial toxicology, the several studies of catastrophes involving large groups subjected to extraordinary exposures (epidemic situations), and in the analyses of morbidity and mortality records.

Clinical and toxicological studies have their principal application in the protection of the industrial worker. The studies usually are supplemented by experimental investigations with animals and men to permit controlled observations of changes resulting from contacts with noxious materials. However, toxic and irritant materials rarely give trouble in an industrial environment until they are present in concen-

trations far greater than ever recorded in the usual urban situation. Consequently, values observed in the plant or obtained in the laboratory are not easily applicable to community problems.

An epidemic is defined as an unusual and widespread occurrence of disease. The catastrophic smog incidents and various accidents fall into this category. Since they represent the extremes, the amount of usable information contributed is therefore necessarily limited.

Analyses of excess morbidity and mortality rates in areas of low and high pollution unfortunately have definite deficiencies. If such data are used, we must assume that uncontrolled factors, such as age, race, and socioeconomic status, have no significance. This assumption obviously is not warranted in the face of considerable evidence to the contrary.

Epidemiological Approach

Although the three sources of data have certain applications, they do not give enough information to permit the formulation of acceptable solutions for the low-level air pollution problems of cities (endemic situations). Since these situations concern the whole community, population studies using epidemiological techniques immediately come to mind. Today, we expect that a rounded investigation will make use of all approaches—clinical, experimental, statistical, and epidemiological studies of epidemic and endemic exposures.

Dr. Phair is professor of preventive medicine and director of that division, University of Cincinnati College of Medicine in Ohio. Dr. Thomson is assistant professor of preventive medicine at the college and senior lecturer of applied physiology, on leave, London School of Hygiene and Tropical Medicine, England. CDC Course in Epidemiology for Nurses

A 3-week course in communicable disease control is offered by the Communicable Disease Center, Public Health Service, Atlanta, Ga., to public health nurses and instructors in communicable disease nursing, beginning May 6, 1956.

The course, designed to increase the technical knowledge and skills of nurses in the prevention and control of communicable diseases, will emphasize epidemiological principles and techniques.

To a limited number of students, field experience under supervision may be available following the completion of the course, May 26.

For further information and for application forms, those interested should write to the director of public health nursing in a State health department or to the Chief, Nursing Section, Epidemiology Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street, N. E., Atlanta, Ga.

therefore, to obtain more specific estimates of the environment for correlation with the patients' reactions. Another reason was the resistance demonstrated daily by smokers and workers exposed to relatively high concentrations of a great variety of irritants. This implied that the observation of apparently healthy or even somewhat incapacitated individuals would not give significant results unless sizable samples were followed for many years.

However, some persons are unusually susceptible—the newly born and those with chronic cardiac or respiratory diseases. Their marked sensitivity due to a low respiratory reserve was notable in the epidemic incidents of London, Donora, and the Meuse Valley. A further advantage can be gained by restricting the choice of subjects to such persons. Since they may be confined or at least significantly disabled, they tend to remain in one locale instead of spending one-third of the day at work, one-third at home, and the remaining third elsewhere. Because exposure in each locale usually differs widely both in degree and kind of pollution, the use of patients with limited mobility diminishes the error of extrapolating environmental measurements made at 2, 3, or more external sampling stations.

As the planning progressed, various considerations led the investigative team to an even more circumscribed approach for the initial effort—use of exact measurements of a small group of selected individuals and their environment. We now believe that until such observations are

available, large field surveys cannot be properly planned or conducted with any hope of success.

The Pilot Study

In our pilot study in Cincinnati, the pollution to which the test subjects were exposed was measured specifically. Persons with obviously diminished respiratory reserve, as indicated by breathlessness, were chosen and followed during January through April 1955, in order to include several periods of high concentrations of air pollutants. These carefully selected individuals were believed most likely to react clinically to variations in degree and amount of contamination.

The selected goal was to prove or disprove the hypothesis: "Fluctuations in air pollution, as measured by soiling of filter paper, are negatively correlated with variations in the patients' well-being as assessed subjectively by diaries and questionnaires and objectively by instrumental methods." Other useful observations were to be made at the same time, for example, the effect of temperature and humidity on cardiorespiratory patients.

We also hoped to find a more precise relationship between air pollution and well-being than is possible by designating pollution as high and low. Carefully observed clinical responses to many different degrees of air contamination might supply a curve demonstrating a more precise relationship. If a specific association could be demonstrated by such an

Nature of disability of 28 patients studied simultaneously, January–April 1955

Age	Sex		Nature of disability					
	Male	Female	Cardiac		Chest		Cardiac and chest	
			Male	Female	Male	Female	Male	Female
50–54	1	3	0	2	1	0	0	1
55–59	5	4	3	1	1	2	1	1
60–64	1	2	0	2	0	0	1	0
65–69	2	2	2	2	0	0	0	0
70–74	2	1	1	0	1	1	0	0
75–79	1	1	0	0	0	0	1	1
80–84	2	0	1	0	1	0	0	0
85–89	1	0	0	0	1	0	0	0
Totals	15	13	7	7	5	3	3	3

The starting point for the classical studies of infectious disease usually has been an identifiable clinical reaction. At first we search for the agent or, if it is known, the demonstration of its characteristics and mode of transmission. Later, we try to determine host, parasite, and environmental factors governing the incidence and prevalence of the disease.

However, man is resistant and resilient. He can withstand and adapt to stresses and insults. This ability differs with age, sex, race, nutritional state, and other variables, but man's reactions are frequently subclinical, nebulous, or transitory. This is particularly true of exposures to toxic materials in the low levels found in community air contamination.

Accordingly, some workers believe air contaminants in low concentrations will never be demonstrated as the primary cause of disease but can be evaluated only as possible contributing factors. The epidemiologist learns early to accept the concept of disease as a summation of a complex of host, agent, and environmental factors. However, the community and industry insist upon exact quantification of single variables, particularly in pollution problems.

Past and present attempts to apply epidemiological techniques to air pollution studies have been elementary and limited in scope. These attempts have dealt with persons in respiratory contact with a complex of materials in widely varying degrees of duration and concentration. The objective usually has been to relate all illnesses having any possible relationship to these exposures, however slight. This goal has been forced upon the investigators because they must work without a definite clinical reaction, specific or nonspecific, associated with such exposures. Accordingly, their findings are received and interpreted with enthusiasm or with doubt, depending upon the desires and motives of their audience.

Today, communities require the extension and refinement of epidemiological observations by carefully comparing selected components of a population exposed to accurately described environmental conditions. The proper selection of indexes, therefore, is all-important. The difficulties encountered in the use of morbidity and mortality rates for the common

respiratory and cardiac diseases are well known.

Still, the average duration of upper respiratory diseases or asthmatic attacks, the mortality rate of individuals with cardiac or pulmonary lesions, and similar measurements may deserve investigation. Whether they will serve or not will require many careful trials. At the moment, no entirely satisfactory study has ever been designed, and it is generally accepted that the search for methods to measure objectively human reactions to air contaminants must continue.

Such studies are not entered into lightly. The goal, essentially, is to relate the incidence, severity, and outcome of a group of clinical reactions, which may have a variety of etiological agents, to the presence or absence of a combination of air pollutants which may vary, absolutely or relatively, from time to time. Since precise morbidity surveys are costly and difficult, and the objectives are so illusory, few have been attempted. None thus far have succeeded in relating human disease unequivocally to differences in air pollution.

Preliminary Planning and Observations

Recognizing the limitations of analytical observations, a project to determine the feasibility of morbidity surveys was planned. The primary objective was to determine if practical investigations could be designed to permit reasonably accurate descriptions of the incidence, prevalence, and prognosis of disease in a population exposed to varying concentrations of air contaminants under urban conditions.

A field team, working under the close supervision of a competent advisory committee, was formed to conduct appropriate trials and test procedures and to appraise possible indexes. It seemed desirable and requisite to explore carefully all the various approaches before planning or embarking on a large-scale investigation.

One reason for this attitude was the considerable doubt of the validity of characterizing atmospheric pollution as high or low. The extreme variability of measurements and the significant overlapping of the observations have long been recognized. It seemed essential,

ometer. For this investigation, we believe that a single interval will be sufficient but the most informative of the three will be chosen after preliminary trials with each subject.

Oximeter. In spite of many known sources of inaccuracy, the oximeter test of blood oxygenation has proved useful for following the progress of patients if cross-checked by simultaneous arterial puncture and gas analysis. In this study where variability from time to time was all-important and the other errors were not critical, it offered the advantage of being independent of patient cooperation, but the value of the observations is questionable.

Respiration. The maximum inspiratory and expiratory pressure test, not yet adequately evaluated, was included because of the rapidity and ease of use in the patient's home. It furnished some information on the relative contribution of viscous and elastic components of the lung to the total resistance and served as an index of patient variation.

Measurement of the Environment

Pollutants. We selected the American Iron and Steel Institute (AISI) automatic smoke sampler to estimate the concentration of air contaminants. This device gives an indication of the atmospheric concentration of "smoke" by aspirating air through white filter paper. Transmission of light through the spots obtained was used as a crude index of the amount of pollution in the patients' environment.

Temperature and humidity. Temperature and humidity were recorded by an 8-day automatic thermohygrograph. The temperature was obtained by a bimetallic unit and the humidity by a bundle of human hairs, each operating individual recording pens. These instruments were checked at weekly intervals by more accurate psychrometers and readjusted if necessary.

Location and servicing. Since the protocol required that the patient's environment be continuously sampled, these mechanisms were enclosed in a soundproof box, placed in or near the bedroom. Although the noise level was not great, the need to protect the instruments and to insure the patient against the possible irritation induced by the constant hum and periodic clicks, forced the development of an elabo-

rate cabinet. It also seemed wise to fuse all circuits to avoid damage to the home or instrument wiring. The nurses checked and serviced the devices at each visit. The machines recorded for a week.

Other measurements. Although smoke was chosen as a crude index of the pollution faced by the patient, it is not to be inferred that it is the only, or even the principal, injurious component. Four Wilson sequence samplers were obtained to ascertain the extent of correlation between SO_2 (or total acid) and the concentration of smoke. This is a satisfactory instrument, but it is not entirely suitable for home installation because of the noise of the pump and the need for daily servicing. Therefore, they were used only in carefully selected locations. There was reason to assume that, except in the neighborhood of a major effluent, the levels of smoke and SO_2 would correlate reasonably well in Cincinnati.

The observations were adjusted to the community measurements of the United States Weather Bureau, the Cincinnati bureau of smoke inspection, and the Public Health Service Robert A. Taft Sanitary Engineering Center. High volume samples were obtained at five points. There were 20 dustfall stations and 3 smoke samplers in regular operation. These records of the external air in Cincinnati were correlated with the household observations.

Statistical Analysis

The technique of multiple linear regression will be used to evaluate the results. A separate regression analysis will be performed for each of the pulmonary function tests and for certain groupings of the subjective symptoms. We assumed that the value of each of these tests and symptoms can be represented by a model of the form

$$Y_i = B_0 + B_1 X_1 + B_2 X_2 + \dots + B_{47} X_{47} + E_i$$

where Y_i is the i th observation of one of the tests or symptoms; and X 's are certain reduced variates identifying lapse of time, patient, and environmental conditions at the time of measuring Y , or during the preceding week; and E_i is the observational error. The effect of time will be removed by a second order polynomial; the effect of absolute differences in patient's

approach, the methodology for further studies could be arranged readily. A failure to show an association with these precise measurements would have a greater significance.

Patient Selection and Followup

Twenty-eight persons were recruited through out-patient departments, private physicians, and institutions for the aged (table). This was the smallest sample expected to supply definitive results. Twice as many would have been better. However, in addition to limitations imposed by the cost of instruments, serious difficulties were encountered in recruiting the proper type of cooperative patient who lived in a significantly polluted area.

Practical considerations required modification of the original criteria. One patient was hospitalized almost immediately, and it was necessary for various reasons to drop four more patients and to select others. Changes of this nature were required throughout the trial. Forty patients were followed for varying periods. Immobilization of the patient in the home became more important, not only because the measurement of atmospheric pollution was most specific there, but also because failure to contact the patient at the proper time upset the statistical plan and increased the work of the staff of visiting nurses.

The lung function tests employed were better adapted to following the progress of chest than of cardiac patients. However, this series contains few chest patients, although they were chosen whenever possible, because:

1. Such individuals appear to remain at work or at least spend more time outside their homes, until the disease becomes advanced and they are hospitalized.

2. They tend to reside in the less smoky areas of the town.

3. Epidemic smog incidents have indicated that cardiac patients are almost equally susceptible to atmospheric pollution.

Furthermore, tuberculous patients were deliberately avoided because the disease is frequently focal. Allergic asthmatics were likewise excluded because, ordinarily, allergens could be expected to vary independently of atmospheric pollution.

In the plan, the group was to be under obser-

vation by December 1, 1954. Unavoidable delays in assembling the equipment and the need for soundproof cabinets forced postponement until early January 1955. We hoped for the occurrence of a sufficient number of inversions to permit an appraisal of the value of this approach.

In this experimental effort, we were primarily concerned with variations in the individual patient's condition. The results do not depend upon changes in the sensitive individuals as a group from the beginning to the end of the trial period or on terminal differences between groups of patients exposed to different levels of air contamination. Thus, the weekly observations of the individual subjects are much more important than his physical condition before and after the trial period. Nevertheless, the clinical assessments were made as complete as possible.

The most important part of the pilot study was to determine and record at frequent intervals changes, however slight, in the patients' well-being. The success or failure in this effort depends largely upon such observations. The patients were asked to maintain a diary recording the occurrence or exacerbation of 12 symptoms. These were selected principally to elicit any unusual irritation of the upper respiratory tract and to record the day-by-day state of the cardiorespiratory system. Some were included to test the validity of the record.

Visiting nurses recorded the pulse, temperature, and respiratory rate, checked the diary, and noted any relevant change in the environment. To reinforce the subjective findings, they made certain objective measurements of lung function at predetermined intervals. If such epidemiological investigations of air pollution are to be pursued properly in the future, simple portable tests, readily adaptable to field requirements, must be developed. This has been given much thought, and some work has been done. Much more work is required, and we believe that this pilot study will be justified by indicating fruitful approaches to this question alone. However, the following were selected arbitrarily for objective measurements.

Timed vital capacity. The proportion of the total vital capacity expelled in 1, 2, or 3 seconds can be determined readily by the Gaensler vital-

level of response will be removed by the corresponding terms in the model for each patient; and relevant environmental conditions are also represented in the model. In the light of these considerations it seems reasonable to assume that the E_i will be normally and independently distributed so that the usual tests of significance can be used. This assumption, of course, can and will be checked.

The sums of squares and cross-products for the variates will be obtained by punch-card equipment, and the resulting matrix will be manipulated with aid of electronic calculation.

Results

It is far too early to report or speculate about the observations. During the course of this initial study, an enormous number of observations were made, and the analyses, as have been indicated, will not be simple nor quickly made. Even this aspect of the project is considered essentially experimental and will require trial with various approaches.

Study Extension and Continuation

From the experiences of the past year, it is obvious that a determined effort should be made to obtain or develop simpler and more sensitive and objective methods for the assessment of respiratory efficiency. For example, the weight of the instruments, particularly the vitalometer, is at the upper limit. Also, it is essential to find a means for measuring the diffusion component of the respiration mechanism in the patient's home. Several other techniques are available, but each must be modified to meet the peculiar requirements of field investigations.

In view of the importance of eye irritation as a symptom in certain situations, we believe it is worthwhile now to consider the development of a quantitative objective method of measuring this reaction to air contaminants. Tentative steps have been made in this direction, but apparently a great amount of careful work will be required.

Furthermore, the continuous recording of the concentrations of particles of respirable size with the AISI samplers in the patient's home,

if feasible, should be supplemented by measurement of gaseous acids. Only a brief trial of the Wilson sequence sampler was carried out in this pilot study. Also, no satisfactory method of silencing has been developed, and this defect, coupled with the need of frequent servicing, limits their use in human habitations.

Summary

The desirability for expanding investigations dealing with the many problems of atmospheric pollution has been accepted by all. They rank among the most important challenges remaining in the field of public health today. The immediate need for safe and practical disposal of airborne wastes and for rational controls cannot be ignored by the community, its industries, or the public health agencies.

Many of the proposed solutions are controversial because the reactions of man on exposure to common air contaminants at the low concentrations customarily found have not been described unequivocally. Lacking acceptable clinical evidence either pro or con, reasonable and rational control procedures cannot be instituted. Additional and more detailed epidemiological studies relating the reactions of man to this hazard are urgently needed.

We have outlined the pilot study now in progress in Cincinnati, in which the atmospheric pollution exposure of the subjects has been measured specifically and the effects of various concentrations have been sought in those individuals most likely to show measurable changes. In the event that an association between pollution and well-being is demonstrated, the methodology for further studies can be described easily. It may even be possible to institute an alarm system based on the behavior of cardio-respiratory or other sensitive patients followed in this way. On the other hand, with the precise measurements employed, a failure should have greater significance.

This approach is only one of many; it may succeed or it may fail. However, until human disease can be shown to be related to community air pollution in an acceptable fashion, the controversies regarding the degree and kind of control for air contaminants will continue.

isopropyl oil, certain cancer-producing petroleum derivatives, and radioactive ores and gases. Significant amounts of recognized cancer-producing chemicals, moreover, have been demonstrated in the exhaust of gasoline or diesel engines and in the atmospheric pollutants of English and American cities. They are contained also in the dust of asphalted roads and in the carbon black constituting a considerable component of automobile tires. The number, variety, and amounts of cancer-producing contaminants of the general and occupational environment have grown during recent decades with the development of modern industry and the increased use of industry-related products. Numerous epidemiological observations strongly suggest that industry-related factors have played an important causal roll in the rise of lung cancers in the industrialized countries of the Western World observed during the last 50 years.

Epidemiology

The general epidemiological evidence supporting this concept is as follows: While a real, definite, and progressive rise in lung-cancer frequency has been noted since the turn of the century, this development revealed marked variations in its time of onset, in its relative degree, and its progression rate in different countries and localities. In some countries, a rise in lung cancer death rates did not become apparent until after 1930 (Denmark, Norway, Italy). In others, and particularly in highly industrialized countries (Germany, Switzerland, England), this change was demonstrable soon after 1900.

English, German, Austrian, and American observations show consistently and significantly higher lung cancer death rates for inhabitants of urban-industrialized areas than those prevailing for rural areas.

Industrial life insurance male policyholders coming from low-income groups and engaged in manufacturing, mining, transportation, and other occupations with possible and often specific respiratory health hazards were found to have lung cancer rates which were 30 to 50 percent higher than those present for general policyholders, mainly composed of white-collar workers and the self-employed.

There was not only a marked irregularity in the progression rates of lung cancer deaths and morbidity for 10 different metropolitan areas in the United States, according to surveys made in 1937 and 1947, but the annual lung cancer death progression rates in the United States were higher for 1914-30 than for 1931-44. Allowing a 20-year latent period, one would expect that the progression of the death rate in recent years would be much higher than in the early period, if cigarette smoking would represent a major causal factor in the rise of lung cancer frequency.

Considering the remarkable variations in the male-female sex ratio at different times, in different localities and different demographic groups ranging even during recent years from 1:1 to 50:1, it is most unlikely that such discrepancies and changes are attributable to fluctuations in the intensity of one single factor, such as cigarette smoking, but appear to be due to alterations in the type and extent of action of a broad spectrum of environmental carcinogenic agents affecting the members of the two sexes to different degrees. Men are for occupational and environmental reasons more intensely and consistently exposed to a variety of known environmental cancer-producing atmospheric pollutants than women.

The various lung cancer-causing agents elicit lung cancers of various structural types. No special type of lung cancer is characteristic for any special carcinogenic factor. None of the main structural types was rare at any time or has any exclusive connection with cigarette smoking.

There does not seem to exist any parallelism between the lung cancer death rate and the per capita consumption of cigarettes for different countries. In fact, the rise in lung cancer death rates parallels as closely, or even more closely, the rise in production and/or consumption rates of motor fuel, coal tar, petroleum products, and several carcinogenic metals and minerals, or the construction of asphalted roads, than that of cigarettes.

Industry-Related Factors

Occupational and epidemiological investigations present additional circumstantial evidence

Environmental Causes of Lung Cancer

By W. C. HUEPER, M.D.

TO BE SCIENTIFICALLY acceptable, any theory on the etiology of lung cancer must reflect a critical, balanced, and competent analysis of the entire epidemiological, medical, and experimental evidence concerning the types and environmental distribution of and contacts with all known or suspected exogenous agents incriminated in respiratory carcinogenesis for environmental, occupational, or medical reasons. It is only through such scrutiny that significant and worthwhile information may be obtained as to the relative role which the various individual respiratory carcinogens have played and are playing in the production of lung cancer. The following facts and observations form an important and integral part of such an assessment.

A large amount of factual and circumstantial evidence of epidemiological, clinical, pathological, and experimental types incriminates a number of general environmental and specific occupational air pollutants in the causation of cancer of the lung. Exposure to these agents exists for considerable parts of the population in general as well as for large groups of industrial workers. Epidemiological observations on hand indicate that only a part of the environmental agents which may cause lung cancer are

known. However, an appreciable number of them have been identified, such as dusts and fumes of nickel, chromium compounds, arsenicals, asbestos, coal tar, soot, vapors or mists of

Hueper, W. C.: A quest into the environmental causes of cancer of the lung. Public Health Monograph No. 36 (Public Health Service Publication No. 452). 54 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1955. Price 45 cents.

Dr. Hueper is head of the Environmental Cancer Section of the National Cancer Institute, Public Health Service, chairman of the Cancer Prevention Committee of the International Union Against Cancer, and a past president of the American Society for the Study of Arteriosclerosis. He is the author of more than 200 publications on environmental cancer and related subjects, including the book "Occupational Tumors and Allied Diseases," published in 1942.

the lips and oral mucosa are constantly bathed in the tarry liquor oozing from the tip of the cigarettes and despite the contact of these parts with the smoke coming from the cigarettes, there is no statistical association with cancer of these parts.

The claim that no tarry material exudes from the cigarette tip cannot be taken seriously, considering the well-known fact that chronic cigarette smokers have notoriously dark-brown-stained fingers. There is, on the other hand, not a single case of cancer of the fingers attributable to cigarette tar available, which would form the equivalent to the numerous cases of coal tar cancers of the hands placed on record. Such a lack of confirmatory medical evidence cannot conveniently be disposed of by assuming a specific "immunity of the skin of the first three fingers" to tobacco tar.

The claimed absence of a positive association between lung cancer and the habit of inhaling cigarette smoke also is inconsistent with the rule that the incidence rate of occupational cancers increases with the intensity of exposure to a carcinogen. The medical considerations on cigarette-smoke cancer of the lung thus reveal a number of serious and fundamental defects and contradictions.

Carcinogenicity of Industrial Agents

Experimental investigations have furnished ample proof of the carcinogenicity of many of the agents involved in the production of human respiratory cancer of occupational origin.

Such an experimental evidence is available for coal tar, pitch, soot, various mineral and petroleum oils, nickel, and radioactive substances. For the carcinogenic action of constituents of coal tar there exists for instance, a large mass of experimental observations made on various species, such as mice, rats, rabbits, dogs, and chickens. Specific carcinogenic polycyclic hydrocarbons, moreover, have been isolated from coal tar and pitch, soot, mineral oils, and carbon black, and such findings have been confirmed by various investigators.

The experimental evidence concerning a carcinogenic action of tobacco tar, on the other hand, is remarkably uncertain. There exists a

considerable discrepancy in the observations made by various investigators as to its carcinogenic action on mice and rabbits. While the majority either did not find any or a very mild carcinogenic effect when tobacco tar was applied to the skin of mice or rabbits, two groups of investigators reported remarkable results in this respect. It is rather disconcerting that the latest of these reports made only a year ago could not be confirmed by subsequent investigators using a similar technique and time of application of the tobacco tar to the skin of mice.

The best that can be said about the experimental evidence on hand regarding carcinogenic properties of tobacco tar is that it indicates the presence of mildly carcinogenic agents in cigarette tar through the use of hyper-reactive animals. There is no evidence that these observations of the skin of a strain of selectively inbred mice have any equivalent in man. Thus the practical importance of these observations as to cancer of the human lung is at present uncertain.

Conclusions

1. The total epidemiological, clinical, pathological, and experimental evidence on hand clearly indicates that not a single one but several if not numerous atmospheric pollutants are to a great part responsible for the causation of lung cancer.

2. The available data do not permit any definite statements as to the relative importance of the various recognized respiratory carcinogens in the production of cancers in the general population. Additive, cumulative, and synergistic effects of several of such agents are a distinct possibility.

3. Observations on occupational respiratory cancers, on the other hand, indicate that in restricted occupational groups exposed to well-defined and highly potent respiratory carcinogens all or most of the respiratory cancers found are attributable to one single carcinogenic air pollutant.

4. The widespread presence of industry-related atmospheric pollutants of recognized carcinogenic properties suggests that the recent alarming rise in lung cancer frequency espe-

in support of industry-related factors as important causal agents in the production of lung cancer.

An analysis of lung cancer frequency among members of seven large industrial groups lists nonferrous metal workers with the highest rate, followed by transportation workers, while farm laborers have the lowest rate. Other investigations indicate that workers exposed to soot from coal- or oil-burning furnaces or powerplants, to metal fumes and dusts or arsenicals, have excessive lung cancer death rates. Included in these occupational groups are operating railroad workers, engineers, stokers, chimney-sweeps, oilers, furnacemen, mechanics, welders, polishers, patent fuel workers, marine engineers, wipers, foundry workers, gashouse workers, tar workers, road workers and asphalters, sheet-metal workers, boilermakers, crane operators, smelter workers, molders, boiler scalers, lathe workers, iron ore miners, grain dockers. Since the total number of members of such occupational groups is considerable, it cannot be maintained that occupational cancer hazards account for only an insignificant portion of the total lung cancer deaths. It is, moreover, evident that abnormal occupational lung cancer hazards seem to exist only for certain groups of workers and that for this reason they must be related to exposures to definite, specific, and identifiable substances. There is scarcely any likelihood that such occupational differences in lung cancer liability are attributable to fundamental differences in cigarette smoking habits between members of the various occupational groups.

Occupational Groups

Occupational cancers of the respiratory organs (lung, larynx, nasal cavity, and nasal sinuses) provide conclusive evidence of the existence of industry- and occupation-related respiratory cancer hazards for members of well-defined worker groups having contact with specific agents.

Such respiratory cancer hazards have been demonstrated for retort workers of gas manufacturing plants and coke ovens, for workers employed in crude paraffin oil pressing operations, for isopropanol manufacturers, for nickel refinery workers, chromate manufacturers and

chrome pigment handlers, for arsenical insecticide producers and users, for asbestos workers, and radioactive ore miners. The lung cancer attack rates for members of these occupational groups are many times those found for the general population of same age and sex. While the great majority of the victims of occupational respiratory cancer are males, because only males are employed in most of these hazardous occupations, whenever females also were employed, such as in the asbestos industry, and have the same type and a similar degree of exposure, there is a trend toward an equalization of the lung cancer attack rates for the two sexes.

Exposures to occupational respiratory cancer-producing agents are sometimes characterized by a typical symptom complex involving not only the respiratory organs but also other tissues and organ systems. The symptom complex related to coal tar cancer provides a striking illustration of the value of this type of medical evidence in support of a specific etiology of a lung cancer.

Medical evidence amply attests to the fact that contact of the skin with coal tar pitch, asphalt, soot, creosote, and tar oils has been responsible for several thousand cases of occupational cancer of the skin, scrotum, and lip. There are, moreover, important cutaneous stigmata characteristic of occupational contacts with these products. These manifestations form a well-defined symptomatic coal tar cancer pattern consisting of chronic dermatitis, comedones, folliculitis, hyperpigmentations of the skin, leukoderma, cutaneous atrophies, warts, papillomas, cornified horns, and light hypersensitivity. Since respiratory exposure to coal tar fumes always entails also cutaneous contact with this material, pathological symptoms from both the cutaneous and respiratory systems combine in the composition of the symptom complex elicited by exposure to coal tar and related problems.

In my opinion, the medical evidence supporting a major role of cigarette smoking in the causation of lung cancer, on the other hand, is inadequate. It is surprising to note the absence of positive statistical associations between lung cancer and cigarette cough, although this latter symptom is clinically characteristic of chronic chain smokers. Despite the fact that

Epidemic Outbreak of Poliomyelitis in Puerto Rico

By JUAN A. PONS, M.D.

SINCE the establishment of poliomyelitis as a clinical entity in Puerto Rico in 1928, sporadic cases have been reported each year uniformly throughout the island, without significant concentration of cases, except for the years 1942 and 1946, when the disease assumed epidemic proportions, with 117 and 307 cases, respectively. An annual average of 50 cases has been recorded during the last 10-year period. A total of 31 cases with 4 deaths, uniformly distributed among 18 municipalities, was reported during the year 1953. In 1954, considerable poliomyelitis was present in Trinidad, Haiti, and Jamaica, and the epidemic in Puerto Rico was probably part of the larger situation throughout the West Indies.

Data collected by the bureau of transmissible diseases control and by the bureau of crippled children of the Puerto Rico Department of Health have been combined and used in the preparation of this preliminary report of an epidemic of poliomyelitis in Puerto Rico.

During the year 1954, up to the end of the month of October, only 21 cases of poliomyelitis, with no deaths, had been recorded for Puerto Rico. Then, in November, a sudden upsurge in the incidence of the disease took place in the municipality of Toa Baja, which has a total rural population of 13,937 (1950 census). During a period of a little more than 1 month, 27 cases, including 4 deaths, occurred

in rapid succession in a semirural area of 7,000 inhabitants, and the epidemic soon spread to the surrounding territory. Forty cases, with 5 deaths, all among residents of rural areas, occurred in the entire municipality, an attack rate of 287 cases per 100,000 rural population.

The epidemic was soon felt in adjacent municipalities and in the relatively distant municipality of Arecibo, as follows:

<i>Municipality</i>	<i>Total cases</i>	<i>Deaths</i>
Bayamon.....	30	3
Catano.....	31	4
Toa Alta.....	6	1
Rio Piedras.....	14	0
San Juan.....	21	1
Trujillo Alto.....	5	0
Juncos.....	4	0
Arecibo.....	22	1
Total.....	134	10

The epidemic form of the disease appeared in these municipalities in a chronological order that bore a close relation to their distance from the first center of dissemination. Scattered cases, which showed no tendency to epidemic concentration, have occurred in various other municipalities, to bring the total poliomyelitis cases for Puerto Rico during the 3-month period November 1, 1954-January 31, 1955, to 218 cases, including 16 deaths.

Besides its characteristic clinical manifestation, the disease has been confirmed by autopsy findings and by isolation of the virus. Through the cooperation of the United States Army Tropical Research Medical Laboratory at San Juan, P. R., type I (Brunhilde) virus has been

Dr. Pons is secretary of health, Puerto Rico Department of Health, San Juan, P. R.

cially among males may in part be causally related to the local and general development of modern industry and the use of its products.

5. While it is possible that cigarette smoking has played a contributory role in this respect, the total evidence available if critically evaluated does not favor the concept that cigarette smoking represents a major factor.

6. Since extensive and expensive efforts are required for obtaining an effective preventive control of the existing respiratory cancer hazards, rigid measures should be taken to discourage the introduction of new atmospheric air pollutants of carcinogenic type, especially if they are of the general environmental variety which are most difficult to control.

An Important Date

Each month your health department and many hospitals, laboratories, schools, clinics, and homes receive a copy of PUBLIC HEALTH REPORTS, mailed to arrive on the 20th, or even earlier, depending upon geographic location of the subscriber.

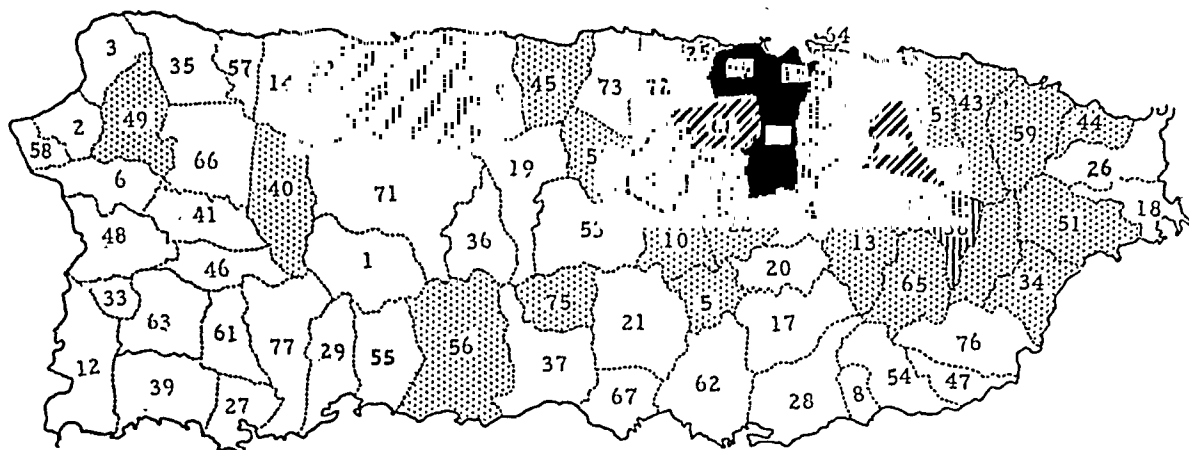

Its pages carry timely research reports, analyses of current trends, new methods, concepts, and ideas, and topical reviews for the busy scientist, teacher, or public health worker. Capsule coverage of important public health meetings, like those of the American Public Health Association, help the PHR reader.

You can have your personal copy promptly. Use the subscription blank on the inside back cover. Let the 20th of each month be an important date for you, too.

**Distribution of poliomyelitis cases in Puerto Rico, by municipalities, during the 3-month period
November 1, 1954–January 31, 1955**

Number of Cases Per 100,000 Population

of age distribution characterizing tropical epidemic poliomyelitis. Five percent of the cases occurred in children under 6 months of age, and practically 90 percent belong to the age group

under 5 years, with especially marked concentration in children under 2 years of age (68 percent). Only 6 cases, or less than 3 percent, occurred in persons aged 10 years and over.

Table 4. Confirmed cases of poliomyelitis in Puerto Rico during the 3-month period Nov. 1, 1954–Jan. 31, 1955, according to severity of involvement

Severity	Cases	
	Number	Percent
Total.....	218	100.0
Severe ¹	103	47.2
Mild ²	71	32.6
Cured ³	18	8.3
Died ⁴	16	7.3
Not specified ⁵	10	4.6

¹ Involvement of one or more extremities, with paralytic manifestations. ² Absence of paralysis. Muscular debility of one or more groups of muscles only. ³ No residual paralysis or muscular weakness. Includes abortive and spontaneous complete recoveries. ⁴ Severe cases terminating in death. ⁵ Data not available. Mostly cases treated at home by private physicians.

Table 4 shows the classification of cases according to the severity of involvement, based on preliminary evaluation at the termination of the acute stage of the disease.

Aiming at uniformity of classification of cases according to severity of involvement, after due consideration and discussion by pediatricians and orthopedic surgeons, the following classification was selected: severe, mild, cured, died, and not specified. The number of cases in each of these groups (table 4) is summarized below, according to whether the cases were paralytic or nonparalytic.

Severity	Number	Percent
Paralytic.....	¹ 119	54.5
Nonparalytic.....	² 89	40.9
Not specified.....	10	4.6

¹ 103 cases; 16 deaths. ² 71 mild; 18 abortive.

From the very beginning of the outbreak, control measures were taken. These consisted

and the corresponding composition of the general population exposed is shown in table 2. The distribution of cases corresponds almost exactly to the urban-rural distribution of the exposed population.

Table 3 shows the age and sex distribution of cases recorded during the period November 1, 1954-January 31, 1955. This age distribution is remarkably similar to the age distribution during the previous epidemics in 1942 (1) and 1946 (2) and follows closely the usual pattern

Epidemiology of Leukemia

By GILCIN F. MEADORS, M.D.

MOST definitions of leukemia incorporate the concept that it is an "invariably fatal systemic disease of unknown etiology primarily involving the blood forming organs . . . characterized by widespread, rapid, and disorderly proliferation of the leukocytes and their precursors and by the presence, almost without exception, at some time during the course of the disease, of immature leukocytes in the blood often in very large numbers" (1).

Leukemia is a rare disease, but because of its fatal character it exceeds as a cause of death many of the acute communicable diseases such as diphtheria, smallpox, and poliomyelitis. In 1950, it was the stated cause of 8,845 deaths out of a total of 210,723 deaths from cancer and 1,452,454 deaths from all causes. The unknown nature of its causation, the fact that it occurs most frequently in the acute form in childhood, and its invariably fatal outcome contribute to making leukemia a matter of interest and concern to the layman and a challenge to the scientist, the clinician, and the epidemiologist some-

what out of proportion to its position in the list of causes of death.

Clinical Characteristics

Leukemia occurs at all ages. It has been reported as present at birth (2) or as diagnosed during the neonatal period (3), and it has been recorded in one woman who was 102 years old (4). It may be fatal in a few weeks, as far as the clinical course is concerned, yet one patient was observed for 29 years with the disease in its chronic form (5).

Morphologically, leukemia is classified as myeloid, lymphoid, or monocytic, according to the type of leukocyte or precursor involved. It is further grouped into acute and subacute, or chronic, types, according to the relative frequency of the immature or blast forms appearing in the bone marrow or blood. The percentage of patients with an unclassified cell type of acute leukemia varies from hospital to hospital and ranges from nearly zero to 40 percent or more. Aleukemic forms of the disease, with normal or depressed total leukocyte counts in the circulating blood, have been described for most cell types.

Leukemia is related to other lymphomas, such as lymphosarcoma, which occasionally may first become manifest clinically as leukemia or which may have a transient or terminal leukemic phase (2). Leukemia also occurs terminally in 20 to 30 percent of the patients with polycythemia vera. Hemorrhage, anemia,

Dr. Meadors, now a private practitioner in Damascus, Md., was formerly chief of the Technical Services Branch of the National Cancer Institute, National Institutes of Health, Public Health Service. This is a revision of a paper presented before the Public Health Cancer Association at the 81st Annual Meeting of the American Public Health Association in New York, November 9, 1953.

Weekly number of confirmed cases of poliomyelitis in Puerto Rico during the calendar year 1954 and January 1955

chiefly in encouraging early diagnosis, with competent free consultation services at all times to private physicians by pediatricians and orthopedic surgeons of the department of health; prompt hospitalization in our district hospitals of suspicious or confirmed cases during the acute stage for observation, confirmation of diagnosis, and proper treatment, with subsequent followup treatment of residual paralysis or muscular weakness at the termination of the acute stage in a convalescent hospital with specially trained personnel and without limitation of hospitalization period required by each individual case; and followup observation of home cases in our diagnostic and plastic clinics.

Gamma globulin has been administered to familial and other intimate contacts under 10 years of age of known poliomyelitis cases, and general instructions frequently have been given to the public through the daily press and radio programs.

registration area, prior to 1933, did not include all of the States and the District of Columbia. The mortality rate has increased during nearly every one of those 18 years, and the rate of increase has remained nearly constant for the entire period. In 1950, the rate for all males was 67.4 and for females 49.8 per 1 million.

The question as to whether this observed increase is "real," that is, whether the risk of an individual developing leukemia is increasing or whether the risk is only "apparently" increasing, is the subject of considerable discussion. It is agreed that a portion of the increase is apparent and due to the changing composition of the population, with a relative increase in the numbers and proportion of older individuals who are known to have an increased risk for developing leukemia. This part of the apparent increase in rate may be estimated and an adjustment of rates made. Another part of the apparent increase is generally attributed to increased, improved, and more frequently used diagnostic services for leukemia, and to more public and professional interest in the disease. The influence of the latter factors has not been evaluated numerically, except for exceedingly crude estimation. And the amount of increase is dependent, to a great degree, on the convictions of the observer. Thus, when the question is restated, "Would you estimate that improved medical care and public and professional interest account for much or little of the increase in mortality from leukemia?" it is obvious that either less equivocal evidence or a direct method for estimating the real increase is required.

Age, Race, and Sex Selection at Death

Gilliam (6) has recently published an analysis of leukemia deaths by age, race, and sex, based on United States mortality experience during 1949. He showed that the risk of death from lymphatic leukemia was higher during each of the first two decades of life than during the third and fourth decades combined. From the fifth decade on there is a marked increase of risk with longevity. The risk of death from myelocytic leukemia is less than that from lymphatic, and there is no secondary peak in risk during childhood. The risk of death

Figure 1. Annual death rate per million population for all forms of leukemia, by sex, United States, 1933-50.

from all forms of leukemia is higher for males than for females in both white and nonwhite races, the male to female ratio being 1.5 for each race. The ratio of white to nonwhite death rates for all forms of leukemia is 2.0 for males and 2.3 for females.

Urban-Rural Distribution

The reported mortality from all forms of leukemia and aleukemia during the years 1944-48 was examined for urban-rural differences in the United States. Average annual mortality rates, according to age and sex, were calculated for urban and rural residence (see table). Urban rates are almost consistently higher than corresponding rural rates for each age and sex group. In diseases for which the precision of diagnosis is dependent on more difficult or specialized procedures, this type of phenomenon is usually ascribed to the relative availability of medical care.

When these data are plotted on a semilogarithmic grid (fig. 2), a changing order of dif-

intercurrent infection and toxemia, and symptoms arising from enlargement of the liver and spleen are characteristic of the clinical disease. The rapidity of development and severity of symptoms, the number and duration of remissions, and the length of survival have classically distinguished the acute from the chronic clinical course. Degree of response to specific chemotherapeutic agents may provide an additional dimension for differentiation of subgroups.

The relative frequency of the acute and the chronic forms in both clinical and autopsy series suggests that the acute form is more common in children and youths, and the chronic form occurs more frequently in older persons. Frequency distributions from these and similar sources cannot be related to the population at risk. The apparent difference in age selection of acute leukemia, in particular, may be of a different order from that currently accepted.

Problems of Classification

As pointed out by Gilliam (6), the classification of leukemia in the sixth revision of the International Lists of Diseases and Causes of Death (1948) is probably as detailed as is realistic for routine recording of deaths. It provides for classification of leukemia by cell type, but no distinction is made between the acute and chronic forms of these entities. Until 1910, the International List included all leukemia under the general term of "anemia." From that date Hodgkin's disease was tabulated under "leukemia" until 1921, when the two entities were given separate rubrics. Between 1938 and 1948, the two forms "leukemia" and "aleukemia" were distinguished by the International List but with no indication of cell type or chronicity.

Sacks and Seeman (7) explored the sources of error in the reporting of leukemia as a cause of death. They came to the conclusion that the system of diagnosis and of classification, as established by the fifth revision of the International List (1938), led to an understatement of deaths from leukemia, but that joint cause selection had no significant effect. Congenital leukemia is known to be overlooked as a cause of neonatal death (2). Other diagnoses, which

possibly have been overlooked, are leukemia occurring in elderly patients who have died presumably from other diseases of old age and in patients of all ages who have died of a fulminating infection relating to an undiagnosed acute leukemia. This latter category has probably decreased in importance because of the effectiveness of antibiotic therapy. Beneficial results from the use of cortisone and chemotherapeutic agents in addition to radiation and blood transfusions make it likely that in the future a larger proportion of patients with leukemia, or suspected leukemia, will be hospitalized at some time during the course of their illness. Increased specificity of diagnosis can be expected and should result in more accurate death certification, followed by less under-recording of leukemia as a cause of death.

In his search for clues to the etiology of leukemia, the epidemiologist must almost perforce be dependent on records designed and assembled for other specific purposes. Sources for clues to the epidemiology of leukemia include mortality records, cancer case registers and surveys, clinical and laboratory records, and results of studies of experimental leukemia. The characteristics of leukemia as determined from these sources are at times confusing, if not contradictory, and the question may be raised as to whether "the leukemias" is not a more appropriate term than "leukemia." The acute and chronic forms of leukemia exhibit such wide differences in the clinical course, response to therapy, age selection, and micropathology that they may be considered as different entities, with some manifestations common to both.

Vital and clinical records should not be neglected as sources of leads for more detailed and specific studies despite the problems involved in diagnosis and classification of individual cases of leukemia and questions that may be raised about the adequacy of such records. The trend in mortality from leukemia, as the stated cause of death in the United States registration area, has been reviewed by Sacks and Seeman (7), who reported an increase in the crude rate from 19 per 1 million population in 1900 to 37 per 1 million in 1940. Trends in mortality rates from leukemia, according to sex, are shown in figure 1 for 1933-50. This period is used because the United States death

Figure 2. Average annual death rate for all forms of leukemia per million white population, according to age and sex, for urban and rural residents of the United States, 1944-48.

cedent events are reported, and the evidence, with regard to some, is mounting that they provide conditions "sufficient" to induce leukemia. Hueper (11) in his text on occupational tumors has provided the most exhaustive consideration of these factors.

Exposure to Radiation

Wynder (12), in a discussion of the practical aspects of cancer prevention, reviewed the evidence for the relationship between the development of leukemia and prior exposure to radiation or to chemicals suspected of having leukemogenic properties. His evaluation of present knowledge of these factors was that "no good evidence was at hand" except with respect to radiation and possibly with respect to benzol. Wynder's conclusion with regard to radiation was based, in part, on analyses by March and Ulrich of the mortality among radiologists from leukemia.

For a 20-year period ending in 1948, March (13) computed ratios of deaths from leukemia to all deaths for radiologists (4.68 percent) and for nonradiologist physicians (0.51 percent). He concluded that the risk of death from leukemia among radiologists was 9 or 10 times that of nonradiologist physicians. Dublin and Spiegelman (14) compared age-adjusted death rates from leukemia for male physicians (11.4 per 100,000) to the rate for the white male population (6.5) and found a ratio of 1.75. Later

they found the number of deaths from leukemia among radiologists during 1938-42 was "several times the number expected on the basis of the mortality experience of all male physicians" (15).

Peller (16) cited age-standardized rates for mortality from cancer exclusive of leukemia and from leukemia for radiologists, all other physicians, and for all white American males of the same age. He concluded that the mortality from leukemia was 3.5 times greater for radiologists aged 35-74 than for other physicians, and 8.5 times that of all white males of similar age. These ratios are somewhat less than the estimates of March. It was his impression that part or all of the increase in the leukemia mortality took place at the expense of the total mortality from all cancer, including leukemia, though he was unable to confirm this from the data available.

The fact that all persons, with even more prolonged exposure to radiation or to chemicals, do not develop leukemia (for example, not all radiologists die of leukemia) suggests that for those who do not succumb, some condition or conditions "necessary" to leukemogenesis are not operative. It has been frequently suggested that presence or absence of a hereditary predisposition might explain some of the vagaries of the behavior of the disease in a human population, that is, that a "cancer diathesis" might be a necessary condition for leukemogenesis.

Genetic Predisposition

Videbaek (17) published in 1947 the results of a genealogical study in Denmark of the families of 209 leukemic probands selected from 310 leukemia patients on the basis of availability of sufficient family data. The study was controlled with the families of 200 nonleukemic persons. Leukemia was found to have been diagnosed in members of 17 of the 209 families of leukemic probands (8.1 percent), and in only 1 of the 200 families of controlled nonleukemics.

Videbaek discussed genetic mechanisms which are consistent with the production of familial aggregates of disease of this order and came to the conclusion that human leukemia seemed to be generally dependent on, among other conditions, a nonspecific hereditary pre-

ference in rates at different ages becomes apparent. The greatest urban-rural differences in mortality rates for white males appear to be at ages 10-14 and 30-39; for white females at ages 10-19 and 25-39. The least urban-rural differences in rates for white male mortality appear to be at ages 20-24 and 0-9; for white females at ages 20-24 and 0-9. The white male experience was the largest in total number and was selected for statistical examination of the variability of urban to rural ratios. Analysis of variance techniques were applied, and the variation between age groups was significantly greater than could be accounted for by chance alone. This does not appear consistent with the hypothesis that urban-rural differences in leukemia mortality are attributable for the most part to urban-rural variation in the availability of medical care.

Clemmesen, Busk, and Nielsen (8) examined the topographical distribution of leukemia in Denmark and published diagrams showing the trend of rates of mortality attributed to all forms of leukemia for the years 1931-45, by sex and by density of population at place of residence. Age composition was not considered. Rates for residents of rural areas tended to be lower than for residents of the capital, with

provincial towns somewhere in between. Annual fluctuations in the rates were wide, however, and the tendency in these data toward an urban-rural difference is not remarkable.

Socioeconomic Distribution of Deaths

From rather meager published data, the higher death rates for leukemia appear to occur more commonly in the more prosperous segments of the population. The two pieces of evidence cited display quite similar trends of increase in rates from lower to higher economic status.

The older data are from the registrar general's report dealing with mortality in England and Wales during the years 1930-32 (9, 10). Decedents were classified according to recorded occupation into five classes: class I, professional; class III, skilled artisan; class V, laborers and unskilled workers; classes II and IV, intermediate and mixed types of occupations or types not readily assignable to classes on either side. Deaths of men and married women only were considered in the analysis. The men were classified according to their own occupation and the women according to the occupation of their husbands. Standard mortality ratios for leukemia deaths in each class exhibited a progressive decrease from class I to class V. This trend is directly opposite to similar ratios computed for deaths from all forms of cancer.

More recently, Sacks and Seeman (7) grouped census tract populations into eight classes according to median monthly housing rental and computed average annual death rates from all forms of leukemia for the years 1939-43. Aside from an irregularity in the trend, probably arising from the small number of cases involved, the death rates from leukemia increased with corresponding increases in average rentals.

Other Etiological Factors

In 1938, Forkner (1) wrote that "in a minority of [human] cases some disease or incident can be found in the patient's life to which the leukemia is sequential in time, and to which, in some degree, it may be related, but in the majority of cases no such antecedent is demonstrable." Each year newly observed ante-

Clues to Suicide

By EDWIN S. SHNEIDMAN, Ph.D.,
and NORMAN L. FARBEROW, Ph.D.

THE IMPORTANCE of the phenomenon of suicide is gauged by the fact that more than 20,000 people take their lives each year in the United States (1). Professional psychiatric, psychological, and social services might save many potentially suicidal persons if the danger is anticipated. In our continuing study of suicide at the Veterans Administration Neuropsychiatric Hospital in Los Angeles County, Calif. (2-4), we are attempting to discover a few of the danger signals.

A basic point of view implicit in our study is that we believe suicide to be motivated by sociologic, cultural, ecologic, psychological, and many other factors (5-8). Another basic point of view is our belief that meaningful studies of

suicide can effectively use the scientific method of experimental control.

Our purpose at this time is to describe an experimental approach in the investigation of psychological factors in suicide and to report a few tentative results. Although our study is limited to the psychological aspects of suicide, it does not preclude other important aspects of the phenomenon studied by Cavan, Dublin and Bunzel, Durkheim (5-7), and others.

Three Types of Raw Materials

Our raw materials are psychiatric case histories, psychological test results, and suicide notes. We have attempted to obtain adequate control data for each category so that statistical comparisons might be made.

Case Histories

The names of adult male suicides were obtained from the weekly lists of all suicides in the Los Angeles County Coroner's Office for the period 1944-53. By checking the names of completed suicides with rosters of former patients of Veterans Administration neuropsychiatric hospitals in the county, we collected the psychiatric case histories of 32 adult male patients who, some time after discharge from the hospital, had killed themselves.

The case histories of the 32 suicides were then checked with the case histories of an equal number of control cases in each of 3 comparable categories of neuropsychiatric hospitalized males: a group of 32 males who had attempted

Dr. Shneidman is chief for research, Psychology Service, Veterans Administration Neuropsychiatric Hospital, Los Angeles, and research associate, University of Southern California. He is also associate executive editor, Journal of Projective Techniques, editor of "Thematic Test Analysis," published in 1951, and author of the "Make a Picture Story" test, mentioned herein. Dr. Farberow is clinical psychologist, Veterans Administration Mental Hygiene Clinic, Los Angeles, and instructor in the extension service of the University of California at Los Angeles.

In its original form this paper was presented at the annual meeting of the American Association for the Advancement of Science, Berkeley, Calif., December 28, 1954.

disposition to cancer. He estimated that this predisposition is present in at least 20 percent of the population and is partly dependent on one or several genes which determine, to some degree, the localization of the cancer.

There was no attempt in this study of genealogies to define the "other conditions" on which the occurrence of leukemia might be dependent. And since familial aggregates of similar order have also been observed for diseases of both infectious and environmental etiology no conclusions can be drawn with reference to the relative importance of genetic factors in the production of human leukemia.

Summary

1. Variations in age, sex, race, and socioeconomic selection of leukemia are reviewed and data on urban-rural distribution of deaths from leukemia in the United States are presented.

2. The finding that death rates from leukemia at certain ages are significantly higher in urban than rural populations of the United States, while at other ages they are of the same order, appears to be inconsistent with a hypothesis that the higher crude rates in urban population can be accounted for by superior diagnostic services in cities.

3. From the published data reviewed there is no evidence that hereditary influences or exposure to leukemogenic agents are mutually exclusive in the etiology of human leukemia nor that they may not be considered jointly as co-leukemogenic factors.

In collecting these data we followed much the same procedure used for obtaining the case histories. The lists of suicides in Los Angeles County were checked against the hospital rosters. Then the previously administered psychological tests on individuals who had subsequently committed suicide were found. Psychological tests on comparable groups of individuals who had attempted suicide, threatened suicide, or who were nonsuicidal were obtained next, and the test results among the four groups were compared.

However, only the test results for 96 of the 128 subjects—the nonsuicidal subjects and those who attempted or threatened suicide—have been analyzed so far. Data for those persons who had been tested and who subsequently committed suicide have not yet been collected in numbers sufficiently large to be subjected to statistical analysis.

Suicide Notes

For our third set of raw materials, we collected 721 genuine suicide notes with the cooperation of the Los Angeles County Coroner's Office. The notes were written during the period 1944 through 1953. Some were written by men, some by women, others by children. The writers were as young as 13 and as old as 96.

There are practical, as well as theoretical, difficulties in obtaining control data to match with genuine suicide notes. A practical difficulty is that notes written by people who have threatened or attempted suicide are hard to obtain inasmuch as they are usually destroyed. To obtain control data, we asked certain individuals, carefully matched with the genuine suicide-note writers, to write the simulated suicide note they would leave if they were going to take their own lives.

The names of the people we asked to participate were obtained from such community sources as labor unions and fraternal groups. In recognition of the moral and ethical overtones associated with suicide, we employed preliminary screening tests, interviews, and other safeguards in order to screen out anyone who might be upset by writing a fictitious suicide note.

Our last step was to analyze the genuine and

pseudosuicidal notes and to relate the statistically significant results to the major psychiatric, psychoanalytic, and psychological hypotheses about suicide.

Results of Research

The following findings come from the research in process and are tentative in nature.

Case History Comparisons

From our studies of the four sets of psychiatric case histories (2), we concluded:

1. It is practically impossible to distinguish a potentially suicidal person from the details of his case history alone, however stressful or traumatic it has been.

2. Seventy-five percent of the subjects who committed suicide had a history of having previously threatened or attempted suicide, although a suicide threat or gesture is not necessarily the mark of a potential suicide.

3. Almost half of the individuals who committed suicide after leaving the hospital did so within 90 days after having been discharged.

As to the first finding, there were few differences in the case history details among the four groups. For example, as many people in one group as in another were only children, came from broken homes, had a history of suicide in the family, and so forth.

From all the comparisons made of the 4 groups we found that only a diagnosis (see table) of reactive depression or paranoid schizophrenia differentiated the 3 suicidal groups (completed, threatened, and attempted suicide) from the nonsuicidal group. Only a history of mental hospitalization among members of the family distinguished the completed suicide group from the other 3 groups. All other comparisons yielded negative results.

Although it is true that not all people who have attempted or threatened suicide go on to commit suicide, the contrary fact—our second finding—is even more striking; that is, there is a large percentage of suicides, specifically 75 percent in our study, who have a history of having threatened or attempted suicide. This fact would seem to indicate that suicidal gestures (attempts or threats) may be considered as danger signals and must be taken seriously.

suicide, a group of 32 who had threatened suicide, and a group of 32 who had no suicidal tendencies. In the 4 groups selected, all 128 subjects were male, white, and most of them were from 20 to 40 years old although the ages ranged from 20 to 69.

We have analyzed the 128 case histories in terms of more than 100 different social, economic, cultural, and psychological categories, and have computed the statistical significance of the differences among the 4 groups. Samples of the categories used for analysis are: family history details, economic level, par-

ents' age at the time of various events in the subject's life, educational and vocational achievements, marital status, and psychiatric diagnosis—an example of which is presented in the accompanying table.

Psychological Tests

For our second type of raw data, we collected test results on the Rorschach ink-blot technique, the Thematic Apperception Test, the Make a Picture Story test, and the Minnesota Multiphasic Personality Inventory, among others.

What might our findings indicate about suicide-note writers?

We interpreted the higher percentage of neutral thoughts expressed by the genuine-note writers to indicate two important, although quite contradictory, feelings on their part and, in addition, to reflect a basic difference in the attitudes of the two groups of writers.

The genuine-note writer has apparently accepted and incorporated the idea that within a short time he will not be alive. He therefore instructs and admonishes in relation to the many details of continued living which he will not be able to pursue himself.

The fictitious-note writer, although he can apparently fantasy the "affect" of suicide, inasmuch as the number of relief statements and *discomfort statements* are proportionately the same, does not take that additional step of converting his fantasy into the "reality" of imminent absence.

In other words, only the genuine suicide-note writer can fantasy his really being gone. At the same time, there is a distinct contradiction between his decision to die and his listing of things to do and his plans for the future. It is as though he were exercising power and command in these directions, as if he somehow were making sure his plans would be carried out. It is a kind of unrealistic feeling of omnipotence and omnipresence on the part of the suicidal individual which may reflect in part some of the confused, illogical, and paradoxical motivations in the entire act.

We noted that the discomfort statements in the simulated suicide notes were only mildly negative but that similar statements in the genuine notes were characterized by deeper and more intense feelings of hatred, vengeance, demand, and self-blame. As used at this time, however, the discomfort measure does not reflect these differences.

Some Words of Caution

In addition to the fact that our project deals only with some of the psychological aspects of suicide, as revealed in case histories, psychological tests, and suicide notes, some other limitations of the study should also be made explicit.

The data we have analyzed so far are re-

stricted to a specific period (1944 to 1953) and to a specific area (southern California) and, therefore, cannot be representative of all times and all locations.

We wish to point out also that, although the 721 suicide notes in the study represent almost 100 percent of the suicide notes written in Los Angeles County during the 10-year period 1944-53, only about 15 percent of the suicides in the county have left notes. Thus, the conclusions about the psychology of suicide from this source may possibly contain some as yet undisclosed sampling biases.

Our clues about suicide are to be taken only as an interim report of tentative findings from a continuing study. We hope, within the next few years, to report more definite information *about the psychological nature of suicide from which a clearer theoretical understanding of its motivations can be obtained and, perhaps, even some clues as to how its prevention and control can be evolved.*

Summary and Conclusions

The following five points are offered as a summary of the findings and implications of this interim report:

1. Three-fourths of our subjects who committed suicide had previously threatened or attempted to take their own lives. This means that suicidal behavior, whether attempted or threatened, must be taken seriously, inasmuch as the next suicidal "gesture" may be the final one.

2. Almost half of the individuals who committed suicide did so within 3 months of having passed an emotional crisis and after they seemed to be on the way to recovery. This means that physicians and relatives must be especially cautious and watchful for at least 90 days after a person who has been suicidal appears to be improving.

3. On the basis of comparisons among psychological tests, it appears that the person who threatens suicide seems to be more emotionally disturbed than the person who attempts suicide, but both must be taken seriously and watched carefully at least for 3 months.

4. The comparison of genuine suicide notes with simulated suicide notes indicates that the

The results of this study do not permit us to state whether the same percentage would apply in a general population. Nevertheless, the finding does suggest that suicidal threats and attempts are a danger signal in the type of suicidal population found in a neuropsychiatric hospital or sanatorium.

Clinical observations in the psychiatric literature corroborate the finding that almost half of the individuals who did commit suicide after leaving the hospital did so within 90 days after discharge. Thus, it appears that even though persons of observed suicidal tendencies are judged to have improved sufficiently to be ready to function in the community again, they are in a dangerous period. It is not possible to state what might be the result of keeping such patients in the hospital another 90 days without further detailed, controlled investigation.

This third finding has implications for timing discharge from treatment and for continuing vigilance in behalf of these emotionally disturbed individuals. It would seem that if a person has been making suicidal attempts or threats, his physician and relatives must be especially cautious for at least 3 months after he appears to be improving and after he seems to be on his way to recovery.

Psychological Test Comparisons

Our study (3) of the psychological tests for those who attempted suicide, threatened suicide, or who were nonsuicidal resulted in the interesting finding that there are differences among individuals heretofore loosely classified as "suicidal." The people who threatened suicide seemed to be more emotionally disturbed than the people who had attempted the act.

There were some differences between people who attempt suicide and threaten suicide. Specifically, individuals who have threatened suicide show more guilt, aggression, irritability, and agitation—in a word, more disturbance—than do individuals who have attempted suicide. Those who have attempted suicide are more like the nonsuicidal mental hospital patients, except perhaps more withdrawn. It is almost as though the attempt itself had operated in an abreactive and therapeutic manner and had lessened the immediate seriousness of the personality disturbance. This temporary relief,

however, does not mean the emotional state ceding suicide will not return.

Genuine and Simulated Notes

From the preliminary comparisons of genuine and simulated suicide notes (4), we are presenting only the results of our application of the Discomfort-Relief Quotient, a technique developed by Mowrer (9).

Mowrer's technique is used to measure relative amounts of discomfort thought units, relief thought units, and neutral thought units contained in case history materials or in statements made during psychotherapy sessions. The thought unit is a discrete idea, regardless of number of words. The Discomfort-Relief Quotient was deemed to be applicable to analysis of genuine and simulated suicide notes for indications of the current emotional ideational state. Thirty-three male, white, Protestant, married, native-born, genuine suicide-note writers were matched man for man by age and occupation, with 33 nonsuicidal simulated-note writers.

The total number of thought units was significantly higher in the 33 real notes than in the fictitious notes, indicating that the genuine note writers apparently feel the need to say more in this last communication.

With respect to the "discomfort" statements or the statements of guilt, blame, tension, aggression, and the like, we found no statistically significant difference between the proportional number of discomfort units expressed by the genuine suicide-note writers and those expressed by the simulated-note writers.

As for the number of "relief" statements, statements which were pleasant, warm, loving, and which denoted relief from tension, we found no quantitative difference between the genuine notes and the simulated notes.

It was in regard to the "neutral" statements—the statements free of expressions either of tension or of release from tension, that the notes revealed the greatest significant difference. The genuine suicide notes contained much the higher percentage of neutral thought units. On inspection, we found them to be mostly statements giving instructions and admonitions or sometimes listing things to do.

The American Heart Association and Federal, State, and local health organizations work together to further research, community service, and education in the cardiovascular diseases.

Cardiovascular Diseases and Public Health

By JOHN W. FERREE, M.D., M.P.H.

- One out of every sixteen persons in the United States has some form of cardiovascular disease.

- One out of every two deaths in this country is from a disease of the heart or blood vessels.

- Approximately 176 million workdays are lost yearly because of heart disease.

- Cardiovascular diseases accounted for the major or secondary impairment in more than 42 percent of those receiving aid under the Bureau of Public Assistance of the Social Security Administration program for the permanently and totally disabled, as shown in a cross-section survey.

- Cardiovascular diseases are long-term diseases; hypertension, for example, has an average course of 20 years.

- In the general population, 3 percent of untreated streptococcal infections are followed by rheumatic fever; among those who have had rheumatic fever, the figure can be as high as 50 percent.

- A recent study of the caseload of the Instructive Visiting Nurse Association in Baltimore indicated that 46 percent of the nonmaternity cases had some disease of the heart or circulatory system as the principal diagnosis.

All these are persuasive—if coldly statistical—reasons for firmly placing the cardiovascular diseases in the public health domain. The American Heart Association has long recognized the public health implications of heart disease, and the concept of community responsibility in prevention, diagnosis, treatment, and education is basic to its philosophy.

The association regards the person with heart disease as a person with social, economic, and personal problems which bear not only on himself and his family but on the community as well. It follows that these problems lend themselves in great measure to successful attack by organized community effort, long accepted as a criterion for public health action. These cardiovascular disease problems, then, are definitely a public health responsibility.

History

Community action to help the cardiovascular disease patient has from the start been one of the primary concerns of the American Heart Association.

The first organized effort to collect and apply information on heart disease was made by a group of New York physicians whose interest was sparked by pioneer cardiac rehabilitation work being done at Bellevue Hospital. In 1916, they formed the “ancestor” of the AHA, the Association for the Prevention and Relief of Heart Disease. Dr. Haven Emerson, then commissioner of health in New York, was a leading spirit of the movement.

Dr. Ferree is director of community services and education, American Heart Association, New York, N. Y. He was formerly State health commissioner of Indiana.

person about to take his own life includes orders and admonitions as though he had reached a final decision in solving his problems and had accepted the fact that he will soon no longer be around.

5. Calling upon professional psychiatric, psychological, and social service specialists for the treatment of a potentially suicidal person may mean the difference between life and death.

Special Assistant for Medical Affairs

Dr. Lowell T. Coggeshall, nominated by President Eisenhower to be special assistant for health and medical affairs to the Secretary of Health, Education, and Welfare, has been dean of the University of

Chicago division of biological sciences, which includes the university medical school, since 1947. In this position, he directed one of the country's largest biological and medical research centers.

He succeeds Dr. Chester S. Keefer of Boston, Mass., who resigned August 1, 1955. Until July 1, 1955, Dr. Coggeshall was also chairman of the Committee on Medical Sciences of the Department of Defense, and at present he is chairman of the Medical and Scientific Committee of the American Cancer Society.

An authority in the field of tropical medicine, Dr. Coggeshall, then a captain in the Navy, was assigned by the Army Air Force during World War II to the Pan American World

Airways in Africa, where he was responsible for establishing medical services along air routes through Africa and the Far East. Later, he was named special medical consultant to the Secretary of War, and during his tenure in that post was in charge of the Klamath, Oreg., tropical disease hospital for Navy and Marine personnel.

Dr. Coggeshall, born in Saratoga, N. Y., in 1901, received his medical degree in 1928 at the University of Indiana, where he also was awarded the degree of doctor of laws in 1948. From 1935 to 1940, he was a staff member for research in tropical diseases, international health division, of the Rockefeller Foundation. He was professor of preventive medicine of the School of Public Health, University of Michigan, from 1940 to 1941, and was chairman of the department of tropical medicine, University of Michigan Medical School, from 1942 to 1944. He then returned to the University of Chicago as head of the department of medicine.

Foxglove plant "breathing in" radioactive carbon dioxide syringed into surrounding bell jar. Radioactive digitalis will be prepared from the dried leaves for use in tracer studies.

disease. And, certainly as important, informed laymen were needed to organize and coordinate community programs all over America.

In 1948 the American Heart Association was expanded into a voluntary health agency, the only national voluntary health agency devoted exclusively to combating diseases of the heart and circulation. Laymen and professional persons not previously eligible were admitted to membership and to places on the association's governing bodies for the first time.

At present the AHA and its affiliates have a voting membership of about 25,000, almost evenly divided between physicians and laymen. There are now 56 direct affiliates and more than 350 local chapters, which are largely autonomous in developing programs to meet their own community needs. The national headquarters in New York administers the national phases of the program, maintains a clearinghouse of ideas and suggestions for the work of State and local associations and committees, and provides educational and program guidance materials and services for them.

The program activities of the American Heart Association are financed primarily by public contributions made during the annual February Heart Fund campaign. At least half of the funds received by the national office are spent to support research, which has top priority in the program as the single most important factor by which we hope to conquer or control the heart diseases.

But results of research do not automatically become full-fledged community programs for helping people with cardiovascular disease. And the encouraging news of scientific progress does not announce itself to those who should hear it. To reach them, an educational program is needed.

Guiding the association's triple program of research, community service, and education are three councils, each directly responsible to the board of directors of the association. They are the Scientific Council, the Council on Rheumatic Fever and Congenital Heart Disease, and the Council on Community Service and Education. The councils are subdivided into committees made up of specialists in their particular fields, who, through their combined experience, are able to give advice and guidance on heart programs.

"Tracer" digitalis enables researchers to follow the drug and to study its action after it enters body tissue.

One of the association's first actions was to encourage formation of cardiac clinics similar to the one at Bellevue. Soon 20 clinics were functioning in hospitals and outpatient departments.

Aside from clinic work, the young organization busied itself with fulfilling its other goals and purposes:

"To gather data from wide sources and arrange for its practical application, in education, occupation, and social welfare; to study and develop occupations and vocational guidance for cardiacs: to take a formative interest in workmen's compensation insurance and similar problems affecting cardiac patients; to work constantly for the prevention of heart disease through the dissemination of information and the application of preventive means (as in increased facilities for post-rheumatic throat and dental treatments); to organize cardiac convalescence to provide larger opportunities in existing institutions, especially for youth; to assist in coordinating the various efforts in this field as made by health departments, schools, cardiac classes, special investigators, the Trade School for Cardiacs, etc.; and to encourage the formation of branch associations."

By the early 1920's, physicians throughout the country had become interested in the association's work. Accordingly, the New York group invited about 100 physicians to a meeting in St. Louis on May 24, 1922, to plan for a national organization. Two years later, on May 20, 1924, the American Heart Association was formally incorporated under the laws of New York State.

The St. Louis meeting defined the objectives of the projected national organization as follows:

"The function of such an association would be to coordinate all activities bearing on the heart problem, to develop new lines of research, to collect and distribute information, to further public health and industrial education, and to develop a sound public opinion as to the true meaning and seriousness of the problem."

Not all of these objectives could be carried out immediately. For more than two decades, the association performed important professional functions. It published a scientific journal, held an annual 2-day scientific meeting,

and established standards in such technical matters as clinical electrocardiography and blood pressure readings.

Of particular significance were the early and continuing achievements in standardizing nomenclature and criteria for diagnosis of cardiovascular diseases. The first work in this area was done in 1916; it has been carried on by the New York Heart Association, which publishes "Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Blood Vessels." With uniform standards, we were able to learn more precisely the nature and size of the problem we were dealing with.

As more knowledge became ours, two basic facts that were responsible for the association's ultimate change of course began to stand out: (a) that the heart and blood vessel diseases constituted a problem of far greater magnitude than had been supposed, and (b) that much could be done to control these diseases, that the old fatalism could well be replaced by hope and optimism.

From these two premises, it was clear that the public health responsibilities which the association had set out for itself had become even more pressing. Yet the association, a small group of physicians and scientists, was not organized to cope with the multiple problems which cardiovascular disease poses for the individual, his family, and the community, nor was it equipped to get its message of hope to the people.

Moreover, a full-fledged program of research was imperative if the war on heart disease was to move ahead. By the 1940's, research had already contributed to the feeling of optimism regarding heart diseases—cardiac surgery, penicillin and sulfa drugs for the prevention of rheumatic fever and subacute bacterial endocarditis—and it could be counted on to produce other advances.

The time had come for a broad community approach to the cardiovascular diseases. Addition of the lay public to the ranks of those already fighting heart disease was the logical first step. Citizen support was needed to finance research, for the channeling of new and existing information to the public as well as to professional groups, and the development of community services for the patient with heart

In the "pleated balloon" test, which measures vital lung capacity, patient raises top panel as high as possible. This is part of the Cleveland Area Heart Society's cardiac work classification clinic procedure to help measure the patient's work capacity.

epidemiological evidence established the relationship between streptococcal infections and rheumatic fever.

Community Service

Although the research programs can be actively participated in by only a few hundred individuals, the AHA's community service program is entered into by thousands of men and women, physicians and laymen alike.

Because they are planned and carried out locally, heart association services vary from community to community. The American Heart Association sets general policies and gives guidance, and the State or regional affiliate gives its support and help, but the actual work is in the hands of the heart association in the community.

A local heart association does not try to solve all of the community's heart disease problems singlehandedly. "Heart disease will not be conquered by the lone wolf approach" has been echoing in heart association ears ever since it was first declared at the First National Conference on Cardiovascular Diseases, held in Washington in 1950 and sponsored jointly by the American Heart Association and the National Heart Institute, Public Health Service.

In tailoring its programs to the community, a local heart association may work at different times with parent-teacher associations, social

work and welfare agencies, labor unions, business and church groups, and other voluntary and official health agencies. It should at all times maintain a close working relationship with the local health department.

A typical community service program might include clinics for patients with cardiovascular disease, rheumatic fever prophylaxis, rehabilitation services and work evaluation units offering to cardiac patients and housewives simpler work methods, vocational counseling, nutritional guidance for patients with heart disease, and home care.

Clinics

The clinic has long been an important concern of heart associations and frequently serves as a focal point for the entire community program. Although heart associations do not actually operate clinics, they help insure the best possible services for the patient by granting certification to local clinics that meet the standards established by a national AHA committee, as outlined in the AHA booklet, *Recommended Standards for Cardiovascular Clinics*. In addition, a heart association often buys equipment for a clinic or contributes, on a demonstration basis, toward the salary of a medical social worker, a public health nurse, or other professional worker.

Rheumatic Fever Programs

Most heart associations are developing community programs for the prevention, control, and treatment of rheumatic fever. Rheumatic fever committees of heart associations work closely with physicians to encourage the widest use of antibiotic preventive techniques presently available. They support community diagnostic services, cooperate with school health authorities to develop screening procedures, and in some cases sponsor traveling clinics for isolated rural areas. Several such traveling clinics have been organized in cooperation with the State or local health department.

Rehabilitation Program

The cardiac rehabilitation program helps patients with cardiovascular disease to remain independent, self-supporting members of society, thus bringing them psychological as well as eco-

Research

Since 1948, a total of approximately \$13 million has been allocated by the American Heart Association, its affiliates, and their chapters for research support. Affiliates and chapters which make research awards in their own areas do so in addition to their contribution to the national research fund.

The association offers research support at three levels: research fellowships and established and career investigatorships.

Research fellowships are granted to young men at the outset of their careers, for a 1- or 2-year term, to enable them to train as investigators under experienced supervision.

Established investigatorships provide support for a 5-year period to scientists who have demonstrated their capacity in research and have developed to the point where they are independent investigators.

Career investigatorships, now held by three men, provide an annual stipend throughout the productive lives of carefully selected scientists of proved and outstanding investigative capacity and genius.

In addition to these three forms of research support, grants-in-aid are awarded to provide the tools of research—technical aid, equipment, and supplies—to experienced investigators working on a specified program of research.

Epidemiological research—studies of diseases of the heart and blood vessels in terms of their incidence and prevalence among population groups with varying characteristics—is beginning to take its place beside basic or experimental research, for which it supplies the clues. For example, the association of overweight and mortality from heart disease was one of the leads that gave impetus to experimental studies of cholesterol and lipoproteins. Similarly,

Investigator placing heart muscle between the electrodes of a plastic holder, which will be immersed in vessel of warm salt solution (right) and then stimulated to contract rhythmically. As different drugs are added to the solution, their effect on the muscle's action can be observed in detail by instruments which record the force of its contraction and the electrical impulses generated by it . . . to gain a better understanding of how the heart muscle works and to improve methods for treating it when its pumping action is impaired.

justify—these are the goals of the association's program of community service and education."

Education

The educational efforts of the American Heart Association fall into two main categories—programs directed at physicians and other professional groups (nurses, dietitians, teachers, clergymen) and programs directed at the general public and special lay groups (parents, patients, workers).

The AHA education program for physicians is designed to make available the mass of new and existing knowledge in the field of cardiovascular disease. The annual scientific sessions are probably the most comprehensive presentation of developments in cardiology. In addition, affiliated and local heart associations

schedule scientific meetings, forums, post-graduate courses, and other events for the medical profession in their areas, often in cooperation with the local health department and medical societies.

Publications for physicians include two scientific journals, *Circulation*, a monthly, and *Circulation Research*, a bimonthly. These have become outstanding media for reports on clinical and basic science subjects. In addition, the bulletin, *Modern Concepts of Cardiovascular Disease*, reviews a specific cardiovascular subject each month.

Handbooks, manuals, and other materials are also issued to help physicians. These include recommendations for blood pressure determination and for examination of the heart; the previously mentioned book on nomenclature and criteria (prepared by the New York Heart

conomic benefits. A pioneering development in this area is the work classification unit, often attached to a cardiac clinic. Each unit provides a counseling service to which physicians and industry may refer patients with employment problems stemming from cardiovascular disease. Here the patient's work capacity is assessed by a team representing several professional disciplines, as a basis for selective placement in a job where he can perform fully without overtaxing his physical reserve.

Physician watches the "master two-step exercise test" in the New York Heart Association's work classification unit. Patient climbs the steps, turns around, and goes down 20 times while "hooked up" to the electrocardiograph. Immediately after the exercise he lies down and receives an electrocardiograph examination.

Together with other services, such as the sheltered workshop and vocational guidance, the work classification unit does much to aid the physician in the practical management of the patient. At the same time it helps to break down the barriers that still keep many capable

patients with heart disease from productive employment.

In the "Heart of the Home" program, rehabilitation principles have been adapted to the needs of the housewife with cardiovascular disease. Housewives are taught how to simplify their work habits and conserve their strength. Special courses are given by heart associations for cardiac homemakers and for those who frequently come in contact with them—nurses, occupational therapists, home visitors.

Nutrition Program

The problems of overweight and diet have occupied the attention of many local heart associations. A number of heart associations, working with their health departments, have organized weight-control groups, and several have given low-sodium-diet cooking classes.

On the national level, the American Heart Association, in cooperation with the Council on Foods and Nutrition of the American Medical Association and the Food and Nutrition Board of the National Research Council, developed recommendations for more precise labeling of the sodium content of special dietary food products, which were incorporated in 1954 in the official regulations by the Food and Drug Administration. Although neither the American Heart Association nor its branches approve or disapprove of specific dietary food products, local heart associations should be able to refer patients to sources of dietetic foods in the community.

Chronic Illness

Another area of community service concerns chronic illness. Home care programs are being explored now as a way for heart associations to cooperate with other community groups in such projects.

In whatever ways a heart association carries out its program, the underlying philosophy is one expressed by Dr. Martin Cherkasky, chairman of the Council on Community Service and Education: "To help those who suffer from heart disease reap the benefits of ever-expanding knowledge, to help them meet the practical problems which illness creates for most individuals, to help them learn the message of hope which the achievements of recent years fully

are financed by public funds, both agencies are responsible for seeing that the funds are not wasted through overlapping or competitive programs.

"A practical arrangement is to have an officer or board member of the heart association on the health department's advisory committee and to have a member of the board or staff of the health department on the board of the heart association.

"This does not mean that every enterprise must be a joint one; each agency maintains its identity and individuality because each has something different to offer. The broad community representation in the heart association makes it possible for the association to furnish leadership, to act as a pioneer in program development, and to stimulate the official agency to make the best possible use of its resources of money and personnel. Very often the two agencies working together can accomplish more than they could achieve separately."

How does this statement work in practice?

In New York staff members of the statewide heart affiliate spend 2 or 3 days each year in meetings with representatives of the State health department, welfare department, and division of vocational rehabilitation. At these meetings, government and heart association personnel exchange ideas and information on rehabilitation, public health nursing and education, school health, chronic disease, and other areas of mutual concern.

Not only do the groups find they understand each other better, but often new programs develop as a result of these sessions. From the liaison in New York, the heart affiliate undertook a demonstration project in rehabilitation at the suggestion of the State health department. The health department will take over the project—paying the salary of a rehabilitation counselor on the health department team—at the end of the 3-year demonstration period.

Sometimes the financial responsibility for projects is reversed, as in the cardiac work classification unit of the Heart Association of Southeastern Pennsylvania. The Pennsylvania Department of Health finances the unit, which provides for service to individuals whose employment problems are caused by cardiovascular disease.

One of the reasons heart associations find it so important to work with their local health departments, medical societies, and other groups stems from the AHA policy of spending money not for individual care but for community programs in cooperation with others, for demonstration projects where needed facilities do not exist, or for salaries and equipment to supplement the services of some other agency.

Behind this policy is the belief that the association's purposes will not be best served by giving financial aid to individuals to cover the costs of medical or nursing care, hospital bills, or drugs. Tremendous sums, far greater than those available to the association, would be necessary to meet such requirements on a fair and comprehensive basis. Moreover, diverting the association's limited funds to comparatively few individual patients would undermine its ability to carry out the program it has evolved to benefit all heart patients and to reduce cardiovascular disease as a threat to the Nation's health.

Health Department Problems

The American Heart Association recognizes the difficulties faced by health departments in meeting the problems of cardiovascular diseases. Shortage of funds, insufficient personnel, hands full just keeping up the traditional health department functions—these are familiar conditions. Yet, as the communicable diseases fade as a major health problem and the chronic illnesses take their place, changes will be appropriate and possible.

A recent study made in Buffalo, N. Y., reveals that crowding, water supply, and sewage disposal have little bearing on four of the most frequent causes of death—heart disease, cancer, stroke, and diabetes (2). Certainly this is not to say that health departments should lessen their vigilance on the old problems. They will still be with us. And, as the Buffalo study also shows, deaths from infective and parasitic diseases are related to housing, water, and sanitation. But in time, control of these will be left-hand functions of the health department. As the chronic illnesses become more pressing problems, the emphasis will shift.

Until public awareness and financial re-

Association), standards for electrocardiography, and recommendations on cardiac catheterization and angiocardiology.

Audiovisual tools for medical teaching and meetings are a recent development. They include heart models, films, slides, tape recordings of normal and abnormal heart sounds, a three-dimensional visual kit (Cardio-Views), and an audiovisual kit (Cardiac Clinic), which combines slides and a recorded medical discussion.

Most heart associations plan educational meetings, forums, and workshops for other professional groups. Frequently, as in workshops in cardiovascular nursing, these are held in cooperation with the health department and other community agencies and organizations.

Several heart associations have held pastoral counseling meetings for clergymen; and many have brought together groups of teachers, social and vocational workers, occupational and physical therapists, and dietitians and nutritionists to discuss the needs of the cardiac in relation to their particular profession. A number of heart associations conduct special industrial education programs to tell both workers and employers the "cardiac can work" story.

The public education program of the association, conducted on the national and local levels, has been a major factor in creating a climate of optimism and confidence that grows out of a rational understanding of heart disease. Booklets and pamphlets, films, exhibits, and meetings are planned to stress accurate information without exaggeration or distortion, to correct misconceptions, to substitute encouragement and realistic hope for the fear and fatalism of the past, to emphasize the scope of the cardiovascular problem and the belief that heart disease can ultimately be controlled through research, and to urge prompt and proper treatment of heart and circulatory disorders.

The national office provides the general reader with a continuing progress report on advances in the heart program through its quarterly periodical, *The American Heart*, and through its press information services.

Both the national office and its local associations maintain inquiry services to answer specific questions from individuals and professional persons in need of information and ad-

vice. In addition, most local heart associations maintain a speakers bureau to provide well-informed public speakers, usually physicians, to interested groups.

Association-Health Department Relation

At about the same time the American Heart Association became a voluntary health agency, the National Heart Institute came into being as one of the National Institutes of Health. In 1950, lay and professional leaders of the two groups met together in Washington for the First National Conference on Cardiovascular Diseases "to determine what we know about cardiovascular disease and how we can apply this knowledge to prevent and cure it." What came out of the conference became the basis for much of the work that both groups have since done.

This past year, the National Heart Institute and the American Heart Association undertook an educational campaign against rheumatic fever, jointly preparing materials for distribution to health departments and heart associations. The basis of the campaign is a 4-page statement by the AHA Council on Rheumatic Fever and Congenital Heart Disease, entitled "Prevention of Rheumatic Fever and Bacterial Endocarditis Through Control of Streptococcal Infections." This was issued first in 1953 and revised in 1955. Other educational materials in the "Stop Rheumatic Fever" unit (1) include a black-and-white film, discussion guide, and leaflets.

The Manual on Administration and Organization for Affiliates of the American Heart Association clearly spells out the heart association-health department relationship:

"Official agencies are legally charged with the responsibility of protecting the public's health. Heart associations have voluntarily assumed a share in this responsibility and should work closely with official agencies toward their common goal.

"Any programs undertaken by a heart association should be brought to the attention of the health department. A number of health departments have developed extensive programs for the control of heart disease. Because these programs, like those of heart associations,

The Epidemic Climate

By WINSTON H. PRICE, Ph.D.

IN THE 16th century, Fracastoro formulated the idea that communicable diseases were caused by "living agents," a thought that occurred to earlier minds but, except for the scabies mite, without supporting evidence that survived to modern times. Later investigators, such as Snow, Henle, Panum, Budd, Holmes, Semmelweis, and Hirsch, inferred the probable existence of such agents strictly by epidemiological methods. However, it was only after invention of the achromatic microscope that Pasteur, Koch, and their followers, using Henle's principles, demonstrated that microorganisms are the primary cause of certain diseases. This important work put on a firm scientific foundation man's understanding of the pathogenesis of infectious disease.

Since that time many other etiological agents (helminths, protozoans, fungi, bacteria, rickettsiae, and viruses) have been identified with diseases of both man and animals. Principal interest has focused upon the differential disease diagnosis and pathogenesis and the treatment of the patient. In comparison, relatively little attention has been paid to the biological survival mechanisms and mode of transmission of

infective agents in a community, particularly during the endemic prevalence or during the interepidemic period. There has also been relatively little investigation of the factors that determine the fluctuations in incidence and distribution of communicable diseases or of those fundamentals that are of importance in determining whether an infection regresses spontaneously or evolves into an overt disease. There is evidence that such factors as climate and season and the nutritional state and hereditary constitution of the host are factors in the natural history of microparasites, but there is little experimental data to indicate just how these determinants influence the spread and survival of the infective agents.

It was recognized early by such investigators as Koch, Pasteur, and Pettenkofer that, while specific agents caused specific illnesses, many other factors were also important in determining whether an individual harboring the infectious agent became diseased. Later workers have expressed similar views—the most recent, Burnet (1) and Dubos (2). However, although there has been much speculation, science has yet to define the circumstances which determine why in certain infections many individuals become infected but few become diseased.

The importance of the biological approach to epidemiology was fully appreciated by Frost (3). In 1934 Theobald Smith, in his Vanuxem lectures on parasitism and disease delivered at Princeton University, formulated concepts which were fundamental to the explanation of these phenomena.

Hamer (4), Soper (5), Hedrich (6), McKendrick (7), Wilson and Burke (8) and Reed of Johns Hopkins University tried to rationalize the occurrence of epidemics by the use of sta-

Dr. Price is associate professor of biochemistry and research associate in epidemiology at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md. In 1954 he received the Theobald Smith Award in medical sciences. The work reported is being supported by grants from the Public Health Service, Rockefeller Foundation, Office of Naval Research, Atomic Energy Commission, and the Department of the Army.

sources and sufficient personnel make the shift possible, what can a health department do so far as cardiovascular diseases go?

A health department, with little or no extra expenditure of time, money, or energy, can accomplish much simply by becoming heart conscious—being aware of the entire cardiovascular problem and letting this awareness pervade thinking and planning in all service and education programs:

Films taken in mass X-ray surveys can be read for possible heart disease and suspected cases followed up for diagnosis and treatment.

In prenatal clinics, special attention can be paid to pregnant women who have congenital or acquired heart disease.

Programs to control communicable diseases can include control of streptococcal infections.

Laboratory facilities can be used for blood sedimentation rates and antistreptolysin-O titers in suspected rheumatic fever and throat cultures in suspected streptococcal infection; laboratory technicians can be trained in prothrombin-time determination.

Nursing and convalescent homes can be inspected from the point of view of nutritional requirements and physical limitations of cardiovascular patients.

In nutrition programs, emphasis can be placed on counseling as regards various nutritional needs, such as the low-sodium diet for hypertension and congestive heart failure, and on problems of overweight.

In school health surveys, children with congenital or rheumatic heart defects can be discovered. Through followup services they can obtain the care and management possible through a greatly expanded knowledge in the two fields. It is here that the Crippled Children's Program has so much to offer.

Public health nurses can be instructed in the nursing care of cardiac patients.

A clearer picture of the cardiovascular problem can be obtained through careful record-keeping.

In all health education programs, cardiovascular disease can be treated to dispel fear and replace it with a reasonable, more objective viewpoint. Teachers and parents can be informed about the relationship of streptococcal infections to rheumatic fever.

All these are things which health departments can do within their existing framework. A number of health departments, of course, are engaged in major programs related to cardiovascular disease.

The cardiovascular disease studies being conducted in Massachusetts, California, and New York State, among others, are calculated to give us the kinds of information that will more clearly define health department and heart association roles in prevention and control of cardiovascular diseases through organized community effort.

In these heart disease control programs, "prevention" is the key word. "Characteristically," writes Lester Breslow, chief of California's bureau of chronic diseases, "the public health approach to problems stresses prevention. As applied to heart disease and other chronic diseases, prevention includes measures which avert the occurrence of disease (primary prevention) and those which halt or retard the progression of disease into disability or premature death (secondary prevention)."

However much a health department is able to do now, and does do, it can be sure of having the help and support of its neighboring heart association. Heart association and health department alike are both working toward the prevention, in its broadest sense, of cardiovascular disease.

C. for 24 hours or by a blood meal (13). The avirulent phase and its reactivation have been observed in the field, and it, therefore, may be presumed to play a role in the natural history of this agent (13).

This work shows that an infective agent may persist in the host's tissues over a long period of time in a form not detectable by laboratory techniques. In view of this possibility, the failure to detect an agent by the usual infectivity tests does not necessarily mean that the parasite is not present. Accordingly, when studying the natural history of a microparasite, it is desirable, when practical, to test for the presence of an agent not only by infectivity tests but also by challenging animals with a known virulent suspension of the organism being investigated or by interference tests (14). For example, in studying the natural history of a mosquito-borne virus, the failure of a mosquito suspension to cause disease when injected into a mouse does not necessarily mean that the agent is not present. It is conceivable that the agent is there but is in an avirulent, or masked form. This same mouse, challenged one month after the initial test inoculation with a virulent suspension of the virus, may prove to be immune because antibodies were stimulated by the avirulent phase.

Field observations and laboratory experiments with *Rickettsia prowazekii*, the etiological agent of epidemic typhus, have shown that many persons may harbor the microparasite years after infection (15-17). The microparasite may become reactivated and cause Brill's disease, or recrudescent typhus, in the hosts. These persons may then infect human body lice which feed on them (16). Man, therefore, may serve as an interepidemic reservoir for this agent, as originally proposed by Zinsser (15).

The question of latent infections and what activates them is one of the practical, fundamental problems of infectious diseases, both to host and to the scientist seeking to learn how the microparasite survives in nature. The importance of this problem was pointed out by some of the earliest investigators of infectious diseases, and more recently by Shope (18, 19).

The primary objective of this type of study, of course, is to try to determine the factors that initiate infection. Once the disease occurs, the

agent may be carried from host to host in a manner totally unrelated to the activation process. For example, in swine influenza the virus exists in the lung worm which is harbored in the lung of the swine. The virus is in a masked state. Following some provoking experience, the virus is activated; the animal then becomes sick with swine influenza and can spread the agent to other swine by contact (19). With typhus, once a louse feeds on a person who has recrudescent typhus, the louse to man to louse cycle can foment an epidemic.

It is still far from clear why specific microparasites vary in incidence and cause epidemics when they do, and why epidemics subside when they do. In our studies on RMSF, for example, seasonal tests on approximately 3,000 ticks for 4 successive years in an area in Maryland showed that the percentage of infected ticks varied only from 0.2 to 0.3 percent each year. Yet during this time there were each year many nonimmune susceptible animals and a countless number of uninfected ticks in the area. The uninfected ticks from this locality could be readily infected in the laboratory by strains isolated in the area. One possible conclusion is that one or more unknown factors in nature contribute to maintaining RMSF in this locality (20).

Influenza

Profile of an Epidemic

In our respiratory study, approximately 3,000 persons are under intensive observation; 800 of these are student nurses and medical school students in the Johns Hopkins Medical Institutions.

During the winter of 1954-55 there was an outbreak of influenza B in the 800 students. It began the middle of December, reached a peak the middle of January, and subsided about the second week of February. About 20 percent of the 800 subjects were infected with influenza B as determined serologically by the hemagglutination-inhibition test.

Some interesting data have been accumulated for the 240 student nurses in the group. These nurses are between the ages of 18 and 22. They all live in the same dormitory and eat at the same cafeteria. During the influenza B

tistical formulas. Given the number of cases of measles, the number of susceptibles, the total population, and assuming an arbitrary value for contact rates in one time period of 14 days, the number of new cases which will arise in the successive time periods of the same length can be calculated. Epidemic theory of this sort yielded some interesting concepts about the spread of contagious disease. However, for infectious diseases, the practical usefulness of this statistical theory is quite limited (9). It is impossible with these criteria to take into account and to evaluate the many factors influencing the propagation of an infectious agent in nature.

Another approach to the study of the epidemiology of communicable diseases is the mass serologic survey for which Paul has coined the term "serologic epidemiology." This method has proved of value in such diseases as poliomyelitis and yellow fever. However, in recent years it has become obvious that in certain communicable diseases, such as those caused by certain arthropod-borne viruses, the results of the mass serologic survey technique must be interpreted with the utmost caution. There is an immunological overlapping among the various members of the arthropod-borne viruses, and, too, certain of these viruses appear to require accessory labile human serum factors for the neutralization test. While this latter difficulty can be overcome by adding fresh normal human serum to all neutralization tests, there is no way to reduce the error which arises from the serologic relationships among viruses.

At the writer's laboratory in the Johns Hopkins University School of Hygiene and Public Health, we have approached the study of infectious diseases by attempting to analyze some of the ecological factors in the natural history of certain microparasites. Principally, we have been interested in the part played by the infected human or animal and in such phenomena as the origin of the first infection or case of the disease, the relation between infection and overt disease, the interepidemic reservoir, activation of latent infections, and factors in nature that determine the variation in virulence and antigenic composition of the causative agents. In all this work we have tried to use experimental conditions approximating as closely as possible

those that appear to exist in nature. We have used the original isolation of the microparasite whenever possible and infected the experimental host in as natural a way as possible.

Many of our experiments during the past 4 years have been directed at understanding the factors influencing the survival of rickettsiae in nature. More recently, this work has been expanded to include human respiratory and arthropod-borne viruses.

The remaining part of this report is concerned with a general discussion of our results thus far together with the related findings of many other workers. Certainly, the point of view presented is not new, but it is one that has not received as much investigation as it deserves.

Attempts to solve these problems involve long-term studies. For this reason, particularly in our virus investigations, only preliminary data are available. The research program described in this report is a large and varied one. It was specifically organized in this manner in order to train workers in the use of a combined field-laboratory approach to disease problems. We have found that this is best done if the investigator is able to work with different diseases that have different survival mechanisms in nature.

The first experiments deal with the rickettsial diseases, Rocky Mountain spotted fever (RMSF) and epidemic typhus. Subsequent discussion deals with human respiratory diseases and certain arthropod-borne viruses.

Rickettsial Studies

It was established by the classical work of Ricketts (10) and Wolbach (11) that *Rickettsia rickettsii*, the etiologic agent of RMSF, is maintained in nature, first, by transovarial and transtadial passage in various tick vectors, and, second, by infected ticks biting susceptible animals which can then infect uninfected ticks feeding on these animals. Early work by Spencer and Parker (12) and more recent studies in our laboratory have further shown that *R. rickettsii* can exist in its arthropod vectors in a phase that is avirulent for animals (13). Virulence can be restored by passage through one egg or by keeping the tick at 37°

Table 1. The relation between blood serum hemagglutination-inhibition (HA-I) titer, October 1954, and incidence of influenza B, December 1954–February 1955

Persons tested	HA-I titer	Percent showing clinical and serologic evidence of influenza B infection

epidemic. Epidemiological and laboratory studies indicated that in the student nurse group about 85 percent of those who developed influenza B had clinical illness, 15 percent of the cases being subclinical.

Many earlier workers have found that many persons with a high blood antibody titer seem to be more resistant to influenza than those with a low antibody titer. However, this statement is not uniformly true. In recorded instances, persons with high antibody titer have developed influenza and those with low antibody titer have escaped infection. In the student nurse group, many nurses with low blood and nasal neutralizing antibody titers escaped infection although they received as much exposure as those who developed influenza. And some of the infected nurses had much higher antibody titers, both in their serums and nasal secretions, against the epidemic strain.

It is of interest to speculate that perhaps genetic differences result in greater resistance or susceptibility, and we are examining this hypothesis.

Seasonal Incidence

Why most influenza epidemics occur in the winter bears on the whole enigma of the seasonal incidence of many infectious diseases. In the Baltimore area, for example, there is no record of an influenza epidemic between the months of May and November.

It is felt that three factors determine the response of the individual to influenza: exposure

to the agent; antibody titer; and one or more unknown resistance factors. Proposed as a working hypothesis is the theory that the unknown factor is a virus resistance mechanism that is lowered during the winter months.

Studies made in an adult group over a 2-year period, from May to October of each year, in the Maryland area have shown that the influenza virus was not spread by subclinical infections in the group during summer months. Hemagglutination-inhibition titers of paired serums collected during these two periods failed to reveal one case of influenza in a population of more than 2,000 persons. About 10 percent of this group had influenza during the winter months of 1951, and about 20 percent of the group had influenza in the winter of 1952.

If influenza is being spread in this population during the summer months, it does not result in detectable antibody formation. We checked this point since it may have been argued that there were influenza cases during the summer months but for some reason such cases did not result in clinical symptoms.

Not only was no influenza found in our study group during the summer months, as measured by at least a fourfold rise in hemagglutination-inhibition titer, but the virus could not be recovered from these individuals 2 months before the 1952 influenza A-prime outbreak. Throat washings collected from 800 persons in the group the first 2 weeks of October 1951 failed to yield an A-prime isolate as determined by three amniotic chick embryo passages. In these tests each throat washing was inoculated into the amniotic sacs of three chick embryos. After 72 hours, the amniotic fluid was collected and tested for hemagglutination in the conventional manner, using human type O red blood cells. The three negative amniotic fluids were then combined, and this material was inoculated into three more chick embryos and tested as described. The whole procedure was repeated once more. During the winter epidemic the A-prime virus was readily isolated.

In 1954, during the first 2 weeks of November, we failed to isolate one influenza B virus strain from throat washings collected from 500 nurses in the Johns Hopkins Hospital. The attempted isolations from the throat washings were made by passing each washing three times

outbreak approximately 20 percent of each of the first-, second-, and third-year classes showed serologic evidence of influenza B infection. Of primary importance, however, was the isolation in early January of three A-prime strains of influenza virus from three of the student nurses during the influenza B outbreak. The nurses from whom these viruses were isolated all showed at least a fourfold hemagglutination-antibody rise against this virus and were clinically ill with influenza.

None of the other 237 nurses showed any evidence of influenza A-prime infection in serologic tests comparing blood samples taken in October with those taken the end of February and again in April. The hemagglutination-inhibition titers of their serums against these three A-prime isolations were low, 60 percent of them showing titers of less than 1:32. Seventy percent of the nurses showed blood-neutralizing serum titers of less than 1:32 against the A-prime virus. The neutralization antibody titer of their nasal secretions was usually about tenfold lower than the serum titer. These low titers were very similar to those observed when there was an A-prime influenza outbreak in the student nurse population in January 1952. As Francis (21), who was the first worker to find influenza antibody in nasal secretions, originally pointed out, the antibody titer of such secretions is very important if the pathogenesis of influenza is considered.

Here we have a situation in which the virus was present in a group that should contain a relatively large number of nonimmune persons. And yet there was no influenza A-prime epidemic, although conditions were favorable for an influenza B epidemic. The possibility that influenza B somehow kept the A-prime epidemic from developing must be considered, but it is difficult on the basis of what is known to believe that this is fact.

We have compared the virulence of the A-prime viruses isolated from the student nurse population during the peak of the epidemic in the winter of 1952 with the virulence of the A-prime viruses isolated from the three student nurses during January 1955. Samples of nasal secretions and throat washings from the latter three nurses and from three nurses clinically ill with influenza at the height of the 1952 epi-

demie showed no statistical difference in amount of virus. All samples were collected during the first 5 days of the disease and each sample was titrated in human embryonic kidney.

Two isolations from each year were tested. Five volunteers were used for each isolation, 20 in all. The viruses were all in the O phase representing the first amniotic passage. All inoculums contained the same number of particles as determined by titration in tissue culture using human embryonic kidney. The volunteers were between the ages of 19 and 26. They all had serum neutralizing antibody titers of less than 1:32 to the A-prime viruses. Two of them had a very slight neutralizing titer of 1:2 in their nasal secretions.

Eight of the ten volunteers inoculated with the 1952 epidemic strain and 7 of the 10 inoculated with the 1955 A-prime viruses developed clinical influenza. Both of the subjects who had slight neutralizing titers in their nasal secretions developed influenza. Four of the volunteers who did not develop clinical influenza had neutralizing titers in their serums and nasal secretions as high as those who developed influenza. The fifth volunteer who did not develop influenza showed a twofold increase in the neutralizing titer of his serum, but he had no detectable titer in his nasal secretions.

Similar results were obtained when the virus inoculums were diluted thirtyfold and given to another 20 volunteers.

On the basis of these tests there was no difference in the virulence of the strains of A-prime isolated in 1952 and 1955. We, therefore, have no clues as to why the A-prime epidemic occurred in January 1952 but not in 1955 since we have no evidence that antibody levels in the host or virulence of the influenza strains were the important determining factors.

The relation between antibody titer and resistance was further investigated in the 1954-55 influenza B outbreak among the student nurses and medical school students. From table 1 it is obvious that the higher the hemagglutination-inhibition titer of the individual's serum, the less chance he had of showing clinical influenza. The hemagglutination-inhibition titers given in table 1 were observed in October 1954, 2 months before the epidemic started, as measured against the influenza B virus causing the

cated by a bacterial infection might possibly harbor the virus in their lungs. It is of interest that the individuals from whom we isolated the A-prime virus did not have any evidence of clinical infection of influenza, according to their family physicians, for at least a year before their operations. But, here again the possibility of subclinical infection cannot be ruled out.

In support of the reactivation hypothesis, we have found that latent influenza infections in laboratory animals may be activated under certain environmental conditions.

Latent influenza infections have been reactivated in a number of ferrets that had recovered from a previous infection of influenza A-prime and were subjected to cold weather. This phenomenon has been identified by specific serologic tests. The same number of previously noninfected control ferrets showed no evidence of the disease when subjected to the same environmental conditions at the same time. At least two conditions seem essential in demonstrating this reactivation. The ferrets must have recovered from a severe influenza infection, and the influenza antibody titer, as measured by neutralization tests, must be low. It is not clear at present which organ or tissue contains the virus at the time of reactivation. In the only extensive tests made so far, using carefully perfused lungs of ferrets, no active virus was revealed in the lungs. In the tests, 20-percent suspensions of the lungs were passed three times in the amniotic and allantoic sacs of 11-day-old chick embryos. Infectivity was gauged by measuring the hemagglutination titer of the amniotic and allantoic fluids, using chicken and guinea pig red blood cells.

If an activation of a latent influenza infection does occur in nature, the question arises whether the latent virus exists in a fully infective form in some organ such as the lung or whether it exists in a "lysogenic" form. This latter virus phase has been described only for certain bacterial viruses (26).

In this phase, the virus exists in a noninfective phase (prophage) which appears to be attached to the bacterial nucleus. All attempts to detect the virus in this phase by splitting open the bacteria and testing for virus infectivity or by serologic tests are completely negative. When the cell divides, each daughter cell con-

tains this incomplete virus. Under certain conditions, the prophage can be activated to form fully infective particles which are liberated from the cell and can then infect all other susceptible bacteria. This represents a model reservoir virus system, and a great deal of work is now going on in our laboratory, as well as in many other laboratories, in an attempt to see if such a situation exists for animal viruses.

It should, perhaps, be pointed out that the fairly rapid decline in antibody titer in humans and laboratory animals after influenza infection does not necessarily mean that the provirus could not be present in the host. Indeed, if a provirus of influenza did exist, it would not be expected to give rise to antibody formation since the provirus of any system that has been studied is not antigenic as tested by any known laboratory procedures.

Immunology and Virulence

Still to be answered is what determines the immunological and virulent properties of influenza virus in nature.

Some epidemiologists have voiced the opinion that the rise and fall of an epidemic is governed by the virulence of the agent. During the early part of the epidemic, they have speculated, the virulence of the agent may be increased by rapid passage from human to human, but as the number of immune individuals increases there is less frequent passage and the virulence of the strain is decreased.

Webster concluded that such changes in virulence play little, if any, role in determining the rise and fall of epidemic waves (27). His experiments, however, were carried out under laboratory conditions with particular bacterial systems. In the natural state, parasites encounter ecological situations far more complex than in the laboratory, and such situations conceivably can influence virulence. For example, changes in the micro-organism may occur when such agents infect persons possessing antibody.

There is no doubt that influenza isolations do vary in virulence and antigenic composition in an epidemic. In 1952 in a hospital ward at a home for the aged in Baltimore, we made 13 virus isolations during an outbreak of influenza A-prime. Careful study showed that this out-

amniotically in chick embryo and testing for influenza virus at each egg passage by the conventional hemagglutination technique: 302 of these washings have also been passed in monkey kidney tissue culture without yielding any influenza B isolations. Thus, 6 weeks before the influenza outbreak occurred in the nursing group, no influenza B was isolated, although approximately 20 percent of the nurses contracted the virus infection from the end of December to the middle of February. Virus isolations of influenza B virus were readily made during the epidemic by the same methods that failed to yield virus isolations before the epidemic.

Although these results are admittedly based on small numbers, they do at least suggest that in these two instances neither the A-prime virus nor the influenza B virus had been widely seeded before the outbreak. These results are of interest in view of the hypothesis of Andrews (22) that the virus may be seeded in the population before erupting into an epidemic. It is, of course, always possible that the virus may be seeded in some form that cannot be detected by either the chick embryo or tissue culture techniques, or the virus may be in some tissue where it would not be collected by throat washings. Andrews presented his theory, in part, to account for the early summer "flurries" of influenza that have preceded many influenza outbreaks in late fall and winter. In all these instances, after the early summer cases of influenza there were no cases of influenza for several months preceding the epidemic. Although we have no evidence that the virus is seeded during this period, here again we have evidence that with the coming of summer months human cases of influenza stop occurring (22). However, in the late fall there is a sudden outbreak of the same influenza strain that had occurred in early summer.

Survival of Human Influenza in Nature

Much has been written about the biological survival mechanism of human influenza in nature. A good summary of the many hypotheses is contained in a recent article by Andrews (22). Although it is impossible in this article to go into all of the various aspects of the epidemiology of influenza, several points

should be mentioned. First, there is no evidence that a host other than man is concerned with the survival of human influenza in nature. Second, one important survival mechanism of influenza is the spread of the virus from one country to another. But, even if one pictures a yearly swing between the Southern and Northern Hemispheres, influenza A does not break out in Europe every winter (22).

Although it is difficult to find influenza in a country between epidemics, the U. S. Army Commission on Respiratory Disease (23) reported that during World War II it was able to find influenza in the United States practically every month of the year. This being so, it would appear that influenza could be maintained sporadically throughout the year, with an epidemic when the environmental factors were right.

There are also several reasons for believing that the activation of latent influenza virus may be a factor in its survival, as first suggested by Shope (24). This is an extremely difficult problem to investigate because of the widespread nature of this disease and the difficulty of ruling out the possibility of infection from a contact. The fact that the Army commission found sporadic cases of influenza throughout the year does not rule out the possibility that some of the cases represented activation of latent influenza infections, much as Murray's (25) studies in Yugoslavia showed that some of the sporadic cases of louseborne typhus fever were really due to activation of latent typhus infections and not to louse bites.

During the summer of 1954, we isolated by tissue culture methods three influenza A-prime viruses from the lungs of patients who had undergone lung operations for various conditions. These strains were not laboratory contaminants since they did not kill mice, whereas the strains of influenza virus used in the laboratory killed mice readily. Since the last big A-prime epidemic was in the winter of 1952, it is felt that these patients had harbored the virus for at least 1½ years. Of course, this assumption would be difficult to prove because of the everpresent possibility of superinfection.

However, it seems to me that some of the persons who have an influenza infection compli-

vaccination with swine influenza, 8 of the 10 children showed neutralizing titers to swine influenza between 1:64-1:256 (mean titer 1:128). However, their titers to FM1 varied between 1:512-1:4096 (mean titer 1:2018).

Five adults, ages 40 to 45, were injected with the same amount of swine influenza vaccine. These adults had initial titers to swine influenza between 1:64-1:256. Their initial titers to FM1 varied between 1:32-1:128. Three weeks after the injection of the same amount and the same swine influenza vaccine that the children received, they showed titers to swine influenza virus varying between 1:512-1:2048. Their FM1 neutralizing titer varied from 1:512-1:2048 (mean titer 1:1024). These results appear similar to those reported for the mice, since the adults, according to the work of Francis, would have had early experience with swine influenza while the children would not.

This work, therefore, supports the hypothesis of Francis that the initial influenza virus infections orient the antibody response produced by subsequent influenza infections under the experimental conditions employed.

It would appear that this phenomenon is not only of importance in the natural history of influenza, but would also be of great importance in considering how to control this disease.

RI-APC Viruses

Another puzzling problem in respiratory viruses is that concerned with the natural history of the new RI-APC group. Hilleman (33) found that 70 to 80 percent of the recruits entering the Army got the APC infection 9 months after they were inducted. Of those recruits inducted during the winter, 70 to 80

Table 2. The effect on antibody response of intraperitoneal and intranasal inoculation of influenza viruses in mice previously infected with different influenza viruses

Primary infection type	Secondary treatment, intraperitoneal or intranasal, 50 days later	Viruses tested against	Mouse neutralization titer X increase after second treatment ¹

	FW-1-50	Swine	16	4
		WS	2	4
		FW-1-50	0	8

NOTE: The above experiment was repeated 3 times with similar results. Influenza B given as the secondary treatment did not cause any increase in antibodies to WS, FW-1-50, or swine influenza virus.

¹ The serums of 4 mice were pooled for each test.

break arose from the introduction of an infected person into the ward.

Using a combination of 10 A and A-prime influenza viruses and the absorption technique of Jensen and Francis (28), we demonstrated immunological differences among these 13 isolates. For example, an isolate from one patient showed major antigenic components related to the Sweden and Rome prototypes, while another isolate showed major components only to the Sweden and English prototypes. A third isolate was related only to the Rome and Malayan influenza virus prototypes. There was no apparent relation between the antigenic composition of the virus isolated and antibody levels before or after infection.

All viruses isolated were passed five times in chick embryos before being used for the absorption tests. The three differing isolates described were also "purified" by three limiting dilutions in chick embryos, the second chick embryo passage being used for the dilution "purification." This was done in order to work with clones as pure as possible. Viruses prepared in this manner still showed the same immunological differences.

The 13 virus isolates could also be broken up into three groups on the basis of their behavior in chick embryos, ferrets, mice, and by tissue culture. In these tests the isolations also were purified by the limiting dilution technique. Although compared on a quantitative basis at various dilutions, 2 of the strains could not be established in ferrets even after four blind passages; 8 of the strains gave a good reaction in ferrets, and 1 isolation resulted in a mild reaction in the animals.

Some investigators have recently proposed that the recombination phenomenon might be important in determining the virulence and immunological properties of influenza viruses in nature. In this phenomenon, reproduced under laboratory conditions, two strains of influenza virus infect a cell, and some cells yield a virus that is different from the original two infecting viruses (1, 29). However, whether such a phenomenon occurs under natural conditions is open to speculation. Taylor (30) has suggested that perhaps the passage of influenza virus through persons having antibodies to various influenza types would have some part in

determining the immunological and perhaps the virulent properties of influenza strains that appear in nature. Work by Archetti and Horsfall (31) and Gerber and co-workers (32) have shown that Taylor's hypothesis can be made to operate in the laboratory.

In further work, we have experimented on the effect of subsequent influenza infection upon the antibody response of laboratory animals previously infected with various influenza viruses. The objective was to obtain a laboratory model to test further the interesting theories of Francis and co-workers that the initial influenza virus infection is important in determining the type of antibody produced by a subsequent influenza infection. They based this idea on a survey of the influenza antibody titers of different age groups. We used 5-week-old Swiss mice and inoculated them intranasally with influenza A-prime virus (FW-1-50), an A-type virus (WS), or swine influenza. Enough virus was inoculated to kill about 15 percent of the animals in all groups. Fifty days after infection the surviving mice in each group were divided into three groups and inoculated intraperitoneally as shown in a typical experiment (table 2). Antibodies were tested by the neutralization test in mice. It is apparent in table 2 that the first infection determined the type of antibody formed when the mice were vaccinated with the different influenza strains.

It was thought of interest to challenge mice intranasally after observing the intraperitoneal effects, since an intranasal test would approximate the conditions in nature. In these tests the mice had a greater tendency to produce antibody to the second virus infection than the first (table 2). It is felt that the mice were truly infected by the intranasal inoculation, whereas they were merely vaccinated by the intraperitoneal route. This may account for the difference in antibody response.

In order to test whether the above phenomenon might occur in humans on immunization, 10 children, 6 to 10 years old, were injected with a swine influenza vaccine. These children had no neutralizing antibodies against the swine influenza virus when their serums were tested in a dilution of 1:16. Their neutralizing titers varied between 1:64-1:128 against the FM1 strain of influenza. Three weeks after

been thought (36-39). Work in this laboratory has been done on West Nile (WN), Japanese B (JB), Murray Valley (MV), and St. Louis (SL) viruses.

We have found that hamsters infected with Japanese B virus and permitted to recover are protected against a subcutaneous challenge of approximately 100 LD₅₀ of West Nile or Murray Valley virus. Previous failure to observe the cross-protection between these viruses was due to the fact that in all preceding experiments mice were challenged intracerebrally. In order to see whether this immunological relationship affected the natural history of these viruses, the following experiments were carried out.

Three-day-old chicks were infected at intervals with 100 mouse LD₅₀ of JB virus and were later mated. The nestlings of these birds were subjected to further study since work of others indicates that nestling birds have an important part in the epidemiology of these arthropod-borne viruses. The nestling progeny of the infected birds contained antibody to the JB virus which was transferred through the egg from the hen. These nestlings were then infected when 4 days old by subcutaneous inoculation with 1-10 mouse LD₅₀ of WN virus or by the bite of *Aedes aegypti* infected with WN virus. Similar results were obtained with both methods of infection. Birds of the same age, species, and not previously infected were used as controls. The control birds showed maximum viremias to WN virus of approximately 10⁴ mouse LD₅₀, whereas the progeny of the birds previously infected with JB virus showed a maximum viremia of approximately 10 mouse LD₅₀ per 0.03 ml. of blood. Half of the uninfected *A. aegypti* feeding on the control birds became infected with WN virus. The West Nile virus was found in only 4 of the 100 tested uninfected mosquitoes which fed on the birds previously infected with JB virus and then WN virus.

The tests for WN virus were made by incubating the mosquitoes for 14 days, making suspensions of them, and inoculating these suspensions into suckling mice, 4 mice being used for each suspension. In all experiments mosquitoes of the same age and lot were used and were fed at the same time in the same numbers 1 and 2 days before the maximum viremia

as well as on the day of the maximum viremia.

In experiments conducted to test the transmission potential of the two lots of mosquitoes in one-half-day-old chicks, 28 percent of the mosquitoes that fed on the control birds were capable of transmission, whereas only 2 of the 100 mosquitoes tested in the group which had fed on the nestlings previously infected with JB virus were capable of transmitting WN virus.

All of the mosquitoes from this latter lot were also tested for WN virus after their transmission tests. They were kept for 5 days at room temperature and ground up. The suspensions were injected into mice. Two mosquitoes showed evidence of WN infection. All mosquitoes were kept for 21 days before virus transmission to chicks was attempted. Similar results were obtained in the above test system when Murray Valley or St. Louis encephalitis viruses were substituted for Japanese B virus.

These experiments approach conditions found in nature. In certain areas where a large majority of animals and humans have been infected with one type of the viruses mentioned, the serologic overlapping may tend to limit the chances that a related arthropod-borne virus will establish a foothold in the area, the result depending upon the viruses involved. It is also apparent that previous infection with one of the viruses will be of obvious importance in determining whether an individual infected with a related arthropod-borne virus develops an overt disease. In this connection, one wonders whether all the arthropod-borne viruses should be classed as neurotropic viruses. It is perfectly true that some cases result in neurotropic symptoms. However, for every host that develops neurotropic symptoms of Japanese B, Murray Valley, or St. Louis encephalitis, there may well be a thousand infected individuals who show no clinical symptoms (1). The neurotropic virus may be a rare type in the virus population, most of the viruses that make up the various members of this group being non-neurotropic.

The isolation of these viruses by intracerebral inoculation of mice would favor the isolation of any neurotropic variants. It would be of particular interest to compare the viruses thus iso-

percent developed the respiratory infection within 2 or 3 months after joining the Army. RI-APC virus types 4 and 7 appear to be involved.

During a study of 2,015 first-year student nurses, medical school students, and college freshmen in Maryland, Pennsylvania, and New Jersey for a little over 2 years, only 4 percent of them developed APC infections. Methods described by Hilleman (34) were used to detect infection. Blood samples were taken every 4 months over a 24-month period. The APC complement fixation (CF) titers of the serums collected at the first interval were compared with the titers of the serums collected at the subsequent intervals. Since the APC antigen reacts with all types of the RI-APC viruses (35), failure to detect an increase in titer against the APC antigen would indicate that these students did not develop any type of APC infection which resulted in a titer increase. Since we have found that with an APC infection the complement fixation titer remains at an elevated level for at least 4 months, the interval between tests should have been adequate to detect any antibody rise.

In view of the large number of recruits who came down with APC infections, we feel it surprising that so few of our study group showed the same type of infections since 80 percent of them were of the same sex and age as were the recruits and were subjected to similar, but by no means identical, environment.

In the student nurse group at the Johns Hopkins Hospital, four of the students developed infection with type 3 virus of the RI-APC group. Ninety-one immediate contacts, including roommates of these four nurses, were intensively studied by serologic tests and isolation attempts for 5 weeks (34). In spite of the fact that the serums of 71 percent of these contacts showed no complement fixation titer to APC viruses at a dilution of 1:4 or no neutralization titers at a dilution of 1:2 against type 3 virus, not one of the individuals showed any signs of APC infection.

In another study of 1,051 human respiratory illnesses in adults from the outpatient departments of the Johns Hopkins Hospital, Sinai Hospital, and Baltimore City Hospital, which laboratory data showed were not influenza or

of bacterial origin, only 4 percent of the illnesses were found to be caused by RI-APC viruses.

A similar low value has so far been found in 1,115 other persons we have been following in the Maryland area. This group is made up of families, adults with chronic disease, and adults between the ages of 60 and 80 who have no chronic physical ailments. Blood samples are taken every 4 months. The RI-APC complement fixation titer of their serums is then compared to their baseline level. Only 4.3 percent have shown rises in their RI-APC CF titer during the 1-year observation period. These rises would include not only clinical infection but subclinical infection with the RI-APC agents.

All these data would seem to indicate that much more investigation is needed before we can be sure just how important the RI-APC viruses are in the civilian population. It is entirely possible that the RI-APC agents may be of clinical importance in children in the civilian population, but this still would not explain why Hilleman found a 70 to 80 percent infection rate in recruits during their first 9 months in the Army.

We have no clues as yet as to why recruits develop such a high incidence of the disease. A combination of emotional strain, physical activity, and hygienic conditions or physical activity and hygienic conditions alone may be the determining factors, since the recruits are subjected to much more strenuous exercise and poorer hygienic conditions than the student group we are observing.

The work of Huebner and co-workers (35), who observed that the RI-APC viruses can be found in the adenoids and tonsils of many normal individuals, leads me to wonder whether activation of latent infections may also enter into the survival mechanism of these viruses in nature.

Arthropod-Borne Viruses

Serologic Relationships

Recent work by several investigators has revealed that certain arthropod-borne viruses are more closely related immunologically than had

above circumstances to the exclusion of the predominating WN particles. This situation would lead to a new antigenic WN virus population. If some of these virus particles were to multiply in another species of mosquito vector than can support the growth and transmission of the WN particles now predominating in nature, this insect vector could act as a further selective medium and give rise to a much different virus than the existing WN virus.

In view of what we know about the biology of viruses, such a speculation must be considered in a discussion of the natural history of arthropod-borne viruses.

Survival Mechanism

The big question that remains to be solved concerning the biological survival mechanisms of the arthropod-borne viruses is how they maintain themselves between epidemics. In spite of the brilliant work of the Rockefeller Foundation, we still cannot answer this question for yellow fever, nor indeed for any arthropod-borne virus. In this country, western equine encephalitis poses a similar problem. No ecological complex has as yet been described which will satisfy all the requirements for an inter-epidemic reservoir. It is possible that the western equine encephalitis virus is harbored by overwintering mosquitoes. Another possibility is that the activation of latent virus infections in the animal host may play a role in the survival mechanisms of some of the arthropod-borne viruses.

Many experiments in this laboratory carried out with various species of hard ticks as possible reservoirs for western equine encephalitis have been entirely negative. However, we have observed in this laboratory that Japanese B virus loses its infectivity for a time when grown in mosquito tissue culture. The methods used would have detected about 10 Japanese B virus infective particles. When active virus appears, the increase is much greater than could be accounted for on the basis of a few infective particles multiplying and giving rise to more infective virus. It appears that in the mosquito vector this virus goes through an eclipse phase similar to that described for many animal viruses in animal cells as well as for bacterial viruses in bacteria (1). Similar results have

been reported for Murray Valley virus in *Culex annulirostris* by McLean (40). These findings, therefore, together with the fact that the multiplication of these arthropod-borne viruses in their insect vector does not appear to damage their cells, make one consider the possibility that in a few mosquitoes the virus may exist in a provirus-like state (26). In this phase the virus would be noninfective and nonantigenic under all the usual experimental conditions, but it could be activated into infective virus under certain conditions.

Conclusion

Although the task of curbing epidemics rarely confronts us in the United States, a major responsibility of public health today consists of anticipating and preventing epidemics. This phase of preventive medicine needs to be supported by studies of the interepidemic history of infectious organisms.

lated with those isolated by chick embryo techniques and various tissue culture procedures.

This problem is important. If the three viruses are not truly neurotropic, the pathogenesis of these diseases would have to be viewed in a different light, and the failure of most individuals to show neurotropic symptoms would not be due primarily to the resistance mechanism of the host but to the virus which infected the host.

This immunological relationship between arthropod-borne viruses may also have practical application in working out vaccination procedure against certain of these arthropod-borne viruses. For example, the killed Japanese B vaccine now in use gives little protection against the virus as measured by its ability to elicit neutralizing antibody. However, we have observed that if the same amount of killed JB vaccine is given to persons who had no previous exposure to JB virus but who had a previous WN infection, a considerable increase in JB neutralizing antibodies is observed (table 3). Serum samples of the 14 subjects were tested before treatment. None of their serums diluted 1:2 neutralized 30 mouse LD₅₀ of JB virus. Six weeks after the subjects had been infected with West Nile virus or injected with killed Japanese B vaccine, they were given a subsequent intramuscular injection of the killed JB virus vaccine. All serum dilutions were made in fresh normal human serum. None of this latter serum neutralized 30 mouse LD₅₀ of JB virus when diluted 1:2. The values in table 3 give the maximum neutralization titer after the initial treatment and 6 weeks after the subsequent killed JB vaccine injection. Weekly blood samples were taken.

We do not know as yet how long these antibodies will last in such individuals. However, it seems to me that it may be possible by using an attenuated strain of one of the arthropod-borne viruses such as WN, which shows serologic overlapping with many of the other viruses, to immunize the individual in such a manner that he can then be vaccinated much more efficiently with killed vaccines of the more virulent related viruses. It is also possible that if a person had a WN infection and was then vaccinated with JB killed vaccine, he would not only get better

Table 3. The effect of previous infection with West Nile virus on a subsequent injection with killed Japanese B virus¹

protection against JB virus but would have some protection against other related viruses. In other words, WN infection or JB killed virus vaccine by itself would give little if any protection against Russian spring-summer (RSS) virus. But the combination of living WN infection plus killed JB vaccine may result in protection against RSS virus because of the immunological overlapping between WN, JB, and RSS viruses.

Our preliminary data support this hypothesis, and we are now in the process of determining which two viruses will give the best protection against a whole group of serologically related arthropod-borne viruses.

Immunological overlapping may also play a role in the evolution of some of these arthropod-borne viruses. For example, we have shown that if a host has antibodies to Japanese B virus and is infected with West Nile virus the multiplication of West Nile virus may be greatly inhibited.

However, if one infectious dose of WN virus were to contain a few particles that differ in their antigenic composition from the majority of WN particles, that is, if they were less closely related immunologically to Japanese B virus, these particles might multiply in the

Unfinished Business in Maternal and Child Nutrition

By MARJORIE M. HESELTINE, M.A.

PROGRESS in recent years makes it possible to talk now about unfinished business in maternal and child nutrition. Even though we lack precise measures of nutritional status, few people doubt that mothers and children, on the average, are in better nutritional condition today than they were 20 years ago. But the very size of our accomplishments makes it necessary to emphasize that there is unfinished business. Some people seem to think we can afford to forget about nutrition programs for mothers and children and turn our attention entirely to overfed adults and the chronically ill of all ages. I dissent. Let me tell you why.

First, there is the magnitude of the problem. As Dr. Martha Eliot, chief of the Children's Bureau, pointed out to the Association of State and Territorial Health Officers in 1952, this Nation is growing younger faster than it is growing older (1). Realizing that this statement was contrary to the prevailing impression, she went on to say that during the preceding decade, the population over 65 years of age had increased 37 percent but the population under 5 had grown by 55 percent.

Miss Heseltine is chief of the Nutrition Section, Division of Health Services, Children's Bureau, Social Security Administration. Since this paper is based on her address at the 1955 meeting of the Western Branch of the American Public Health Association, the illustrations are drawn largely from the western part of the country.

Because of improved maternal care, the 4 million babies that are born annually may be spared many of the hazards of delivery and early infancy. But their birth certificates carry no guarantee that they will receive the daily dietary allowances recommended by the National Research Council. If an infant is to get the food he needs for optimal growth (please note that I do not say maximal growth, a point I shall discuss later) under conditions that make for good physical and emotional development, parent education in nutrition must go on and on as long as women have babies. Then, too, there is sufficient indication that what happens during childhood has a bearing on health during adult life to warrant continuing attention to maternal and child nutrition if only for its long-range influence on health problems of later maturity, which are now so much in the limelight. Public health nutrition services should be directed toward the older age groups, but programs should continue to serve maternal and child health as well.

My colleagues in State child health and crippled children's programs offer another reason for urging no diminution in maternal and child nutrition work: Generalized undernutrition, they say, can still be found among children in the United States, and even cases of dietary deficiency disease are seen occasionally from cultural groups that have not shared in the widespread economic prosperity. It is true that we have to look much more sharply for instances of malnutrition than we once did, but those we see are all the more dis-

trend to earlier feeding of solid foods are more probably social than they are nutritional or medical." And in case anyone thinks that parents take their pediatrician's recommendations without demurring, you should know that 59 percent of the pediatricians reported that they "experienced considerable pressure on the part of the mothers for the early introduction of solid foods." The consensus was that there is no physiological basis for introducing solid foods before the age of 3 months.

For Healthy Teeth

Still another aspect of maternal and child nutrition about which we need to know much more is the relation of nutrition to healthy teeth and to their resistance to caries. It seems to be well established that the development of structurally sound teeth is dependent on a supply of nutrients that have their source in the ingested food. The argument begins on the question of the effect of diet on the susceptibility to caries of the fully formed tooth. Many discussions have been devoted to that topic, but the net result, it seems to me, is that the proponents of the various schools of thought have become more convinced than ever of the validity of their evidence whereas neutrals have become only more confused.

Fortunately, research on this question continues, and the prospects of an answer become brighter through the use of such new tools as electron microscopy and radioactive tracer techniques. There is certainly some indication from recent studies that enamel is permeable both from the oral cavity and the bloodstream.

Diet and Pregnancy

We need to know more about the relationship of diet preceding and during pregnancy to the well-being of the mother and infant. Teams of research workers in various medical centers have approached the study of nutrition during pregnancy quite differently and, as might be expected, have often failed to confirm each other's findings. Does that mean that we should no longer claim that what a woman eats during the maternity cycle is important? A question as direct as that was put by a nutri-

tion workshop participant last summer to a young obstetrician who had just reported that a large-scale study had failed to reveal major differences between the nutritional condition of women who had had good diets and those who had had poor diets during pregnancy. As this physician was known to be an expectant father, he was asked: "What are you advising your wife to eat?" Thereupon, the nutritionists listened to the kind of dietary recommendations that they wish every pregnant woman might receive from her physician. His study may not have shown that diets somewhat below prevailing standards of adequacy had had a deleterious effect; but he was well aware of other studies that had shown diet to be important, and he wanted his wife to have the benefit of the doubt.

There would seem to be some rather impressive evidence in regard to the consequences of drastic limitation of calorie intake during pregnancy. Studies in Chicago have shown that when the energy requirements of the pregnant woman are not met, storage of nitrogen in the form of protein does not proceed at a satisfactory rate (8). Other studies indicate that women who are underweight at the beginning of pregnancy and who fail to come within a normal range during the first two trimesters have a higher than average proportion of premature infants (9). Nevertheless, I have been told of a teaching hospital that has only recently abandoned the routine prescription of a 1,000-calorie diet for prenatal clinic patients. The woman who is given such slim rations is sometimes told that it is important to control the size of the fetus. Yet there is impressive evidence that a diet so restricted as to affect the weight of the infant is pretty sure to take its toll on the mother. Periods of famine do result in lower birth weights. They also are likely to impair the health of childbearing women.

Nutrition Education

Thus far, I have dealt only with the need for extending our knowledge of nutritional requirements and with the importance of putting into practice the concepts that have been evolved by our most authoritative leaders. But in order to put into effect what we know about nutrition, we need to know more—much more—about the

trekking in these prosperous times. The comments of a young nutrition trainee from a so-called underdeveloped country after she had taken part in a dietary survey among low-income rural families in the United States are pertinent here. In a personal letter to an understanding American friend, she wrote: "Speaking of diet, I believe that the poor people of these countries . . . have a diet more deficient than the poor of my country. In a large family of 8 members, one housewife here reported that they spent only \$5 a week for food. This whole family is ill, and no wonder. And like this family, there are others and others. I also have the impression that these people show a greater sadness because they see from so close the comforts that they would like to attain."

The task ahead in maternal and child nutrition falls into two main categories, as I see it. We need to know more, much more. We need to do more with what we already know, and even with hypotheses that we think may be confirmed by research.

Requirements for Optimal Health

Of the many aspects of maternal and child nutrition that we need to know more about and to do more about, one is the matter of nutritional requirements for optimal health at all stages of development. In 1953 the Food and Nutrition Board of the National Research Council issued the third revision since 1943 of its Recommended Dietary Allowances (2). The ink was hardly dry on this revision before the recommendations for protein allowances during the first year of life were challenged as being unnecessarily liberal. A committee of the board is now reconsidering these recommendations, and the Academy of Pediatrics has appointed a committee on nutrition which will direct attention to the matter. These recommendations, which represent "nutrient levels selected to cover individual variations in a substantial majority of the population" and which must never be confused with minimal requirements for an individual, are sure to be revised again and again as research throws more light on nutritional needs.

We need to know much more about satisfac-

tory rates of growth in children. As two research workers said, we need to find the "answer to the important medical-nutritional question regarding the degree of conformity to a norm to be expected on the part of an otherwise healthy child" (3). Longitudinal studies, such as those now under way at the Colorado Child Research Council, have already given us a respect for individual differences (4).

Although it is not easy for Americans to give up our "bigger and better" concept, there are those who are impressed by the questions raised by Prof. R. A. McCance of London. He asks whether the attainment of large size through very rapid rates of growth is in the interests of optimal health either during childhood or in later life. The following statements from one of his lectures may whet your appetite to seek out his provocative papers on overnutrition and undernutrition (5): "Animal husbandmen have bred and fed their animals for rapid maturity and marketable qualities and political husbandmen have come near to doing the same for children. Curiously little work or thought has been devoted to a study of the desirable plane of nutrition for the different years of human endeavor."

Introduction of Solid Foods

If infants are not expected to grow at ever more rapid rates, there may be some revision in our ideas about the time for introduction of solid foods into the diet. The Child Health Center at the University of Washington has pioneered in trying to discover whether there is any difference in the progress of babies given solids by the end of the fourth week and those not given solid foods until the age of 9 to 12 weeks. Two researchers at the center could not detect any significant difference in the development of the two groups of infants in their response to solid foods (6).

Another approach to this question was taken by a group of pediatricians. By means of questionnaires, they obtained information from more than 2,000 of their colleagues in all parts of the country (7). There was general recognition of the trend toward early introduction of solid foods, but as one pediatrician put it: "The major factors underlying the current

cooperate with other agencies in mutually beneficial programs and that they can undertake modest factfinding activities on their own.

As an example of the former, I am thinking of a statewide study of food habits of families with children that was conducted by the New Mexico Department of Public Health and nutritionists in the New Mexico Agricultural Experiment Station (12). As a result of this study, the health department has a much sounder basis for its nutrition programs in behalf of children.

I could cite many examples of the latter, but I will mention only two. A district nutritionist in Florida, with help from the State health department, worked out a device for learning what some of the words that come trippingly on the tongues of prenatal clinic staff mean to the patients. She learned, among other things (13), that to some of the patients "nutrition" is "the man who lays out dead folks." We can well believe that clinicians and nurses in that part of Florida will no longer tell a prenatal patient to "talk to Miss C . . . about your nutrition." In a county health department in California, a Spanish-speaking nurse, with the encouragement of her supervisor and help from a State nutrition consultant, undertook to find out what the Mexican-American families in her district were eating. The data she obtained would not permit an easy generalization. There was as much disparity between low-income and prosperous families as would be found in an Anglo-American group.

In conclusion, let me emphasize that the unfinished business in maternal and child nutrition is to a large extent the business of all public health workers. Seek help from the nutritionists and complain long and loud when you can't

get it. But don't expect the nutritionist to do the job alone.

people to whom nutritional programs are directed.

Nutrition education has come a long way since the days when the nutritionist was a feminine lone ranger, who prepared her own educational material (usually mimeographed, single spaced), jumped into her car, traveled across the State to a county where there might or might not be a public health nurse, rounded up a group to listen to her talk or watch a demonstration, got back into her car, and returned to the State office. In those days, the public health nurse was not expected to know anything about nutrition. If she strayed beyond underlining the appropriate paragraphs about diet in the pamphlet she handed to a parent, she did so at her own risk. Community organization, group dynamics, the consultant-consultee relationship—all these were concepts that she had never heard of. There was no thought given to modifying teaching about foods to fit cultural patterns, for the emphasis was on Americanization. If cream soups were accepted by middle income Anglo-Americans, it was assumed the sooner recently immigrated Mexican mothers learned to make cream soup the sooner they would evolve into 100-percent Americans.

Currently, nutrition enters into the daily activities of many kinds of public health workers. A large proportion of them are equipped by training and experience to deal effectively with the run-of-the-mill nutrition problems, although, of course, they recognize the need for technical assistance from a nutritionist—hopefully one who is accessible enough to give help when it is most desired. Increasingly, nutrition consultation is focused not on what is new in nutrition but on how to make what is old (and as far as we know still true) function in the lives of people. Maternal and child nutrition teaching has been profoundly influenced by the writings of such men as Aldrich, Senn, Richmond, and Spock. Good nutrition is viewed not as an end in itself but as one factor in the development of a sound body and a healthy personality.

Knowing what is considered an appropriate diet for a parturient woman and her infant and why certain values are attributed to certain foods is only the starting point for soundly

motivated education in maternal nutrition. Beyond this, we must understand the ways of life of the people whom we are trying to teach. In work with cultural groups that have different value systems from their own, public health workers have found a new ally in the anthropologist. A paper on midwife training by Dr. Isabel Kelly (10), an anthropologist with the United States Operations Mission to Mexico, provides the following illustration of how a health worker and a social scientist may cooperate in solving a problem:

In certain Mexican villages, the women were unwilling to drink water during the later months of pregnancy or to give either water or fruit juice to their babies. As a result, both mother and child were deprived of essential fluids, and the child did not get the necessary amounts of vitamin C. Dr. Kelly and a nurse midwife worked out this solution: an increase in consumption of the herb teas that are an accepted part of the diet of these people and addition of an ascorbic acid tablet to the tea before it is given to the babies. The women were quite willing to make these modifications in their habits.

Dr. Kelly does not suggest that the practices found in these villages will persist indefinitely; she merely points out how a practice may serve effectively for the present. As Dr. Cicely Williams, who has done maternal and child health work in many parts of the British Commonwealth, states in an article on nutrition (11). "Many of the customs recorded by social anthropologists are not (as commonly supposed) unalterable but can be replaced by more rational and advantageous behavior once the position has been explained and understood. Often one sees the term 'social and cultural customs' used to dignify habits which are merely the result of ignorance and carelessness."

Health Agencies and Research

Not only can health departments do more about applying what is known in nutrition, they can also contribute to the knowledge that is to be translated into programs. I am not suggesting that health departments should embark singlehandedly on ambitious nutrition research projects; but I am suggesting that they can

Figure 1. Insecticide-impregnated cords installed in a feedroom of a dairy.

were suspended vertically either from the ceiling or from horizontal cords extending from wall to wall (fig. 1).

In dairies and rural areas, the cords were installed at all protected potential fly-resting sites, particularly those within barns, pigpens, calf pens, and chickenhouses. In the rural area tests, treated cords also were suspended in the kitchens and on porches of unscreened houses. Treatments in military food establishments included complete installation of cords in the dining halls and partial treatment of the kitchens. In the kitchens, cords were placed so that the affected flies would have little chance of falling into food-preparation sites. Cords also were installed beneath the overhang of the entranceways.

Appraisal of the housefly populations in dairies was accomplished by selecting the highest grill count (5 counts per station) from each

of 4 stations. These stations were not fixed sites but general areas, such as stanchions, entranceways, and feedrooms. The average of the four highest counts constituted the weekly fly index. In the rural areas, 5 grill counts were made on each of 10 premises every week. The highest count at each of the premises was recorded, and the average of these counts was employed as a weekly index. In the unscreened kitchens, total fly counts were recorded. In military dining halls, the weekly fly index was made by obtaining a total count of houseflies found in the kitchen and dining hall. The fly densities were evaluated during the same time interval each week to avoid, as much as possible, variations in fly behavior.

All dairies used in the study maintained herds of 100 to 400 cows. One dairy (C, fig. 2) received installations of freshly treated cords impregnated in a 7.5-percent parathion

The Use of Insecticide Treated Cords for Housefly Control

By JOHN W. KILPATRICK, M.S., and H. F. SCHOOF, Ph.D.

IN RECENT years, the resistance of houseflies to residual treatments of DDT and other chlorinated hydrocarbon insecticides has stimulated intensive search for new insecticide materials and control techniques. Numerous synergistic compounds have been screened in an effort to develop a chemical formulation effective against insecticide-resistant houseflies (1-3). Other fly control methods include larviciding (4), space spraying (5), and poison baits (6-8).

Baker and co-workers (9) evaluated the effectiveness of DDT-treated cords for housefly control in food establishments, while Pimentel and associates (10) used screen strips treated with high concentrations of dieldrin and festooned from barn ceilings as a means of controlling houseflies in dairies. Variations in these techniques have included the use of cords impregnated with other insecticides, including organophosphorus compounds. Laboratory studies of Fay and Lindquist (11) indicated the type, size, and color of cords most suitable for treatment and the effective concentrations of the dipping solution. Maier and Mathis (12) in 1952 demonstrated that cotton cords $\frac{3}{16}$ inch in diameter treated with parathion gave consider-

able promise as a method of fly control in dairy barns near Savannah, Ga. Further field tests in 1953 in rural areas (13) and in dairy barns substantiated these earlier results. These tests indicated that cotton cords $\frac{3}{16}$ inch and $\frac{3}{32}$ inch in diameter impregnated with parathion produced satisfactory control of flies in dairies and rural areas when the cords were installed at the rate of 8-15 linear feet of cord per 100 square feet of floor area.

In 1954, field studies with cotton cords $\frac{3}{32}$ inch in diameter were designed to evaluate different installation techniques, cord dosages, and chemicals (parathion and Diazinon). Cord installations were tested in dairy barns, rural areas, and military dining halls.

Methods

Cotton cords were treated by immersion in either a 7.5-percent or a 10-percent parathion-xylene solution which, by chemical analysis, showed a dosage of 75-100 mg. of parathion per linear foot of cord. For uniform impregnation, the cords remained in the insecticide solution for approximately 2 minutes. The Diazinon-treated cords were impregnated by dipping them in either a 10-percent or a 25-percent (an estimated 200-250 mg. per linear foot) Diazinon-xylene solution. All cords were installed at the rate of 30 linear feet of cord per 100 square feet of floor area, with the exception of one test with Diazinon-impregnated cords in which the dosage was reduced to 25 linear feet of cord to 100 feet of floor space. The cords

Mr. Kilpatrick and Dr. Schoof are entomologists with the Technical Development Laboratories, Communicable Disease Center, Public Health Service, Savannah, Ga. Dr. Schoof is chief of the Biology Section of the laboratories.

Figure 3. Control of houseflies in dairies with 12-month-old parathion-treated cords (1953).

and fly densities remained at very low levels throughout the entire season. The second dairy (T), treated with cord freshly dipped in a 7.5-percent parathion solution, showed an immediate reduction in the fly population, but control levels were not reached until several weeks after treatment. However, once control levels were obtained, low fly populations prevailed the remainder of the season. The third dairy (Ra), treated with cords freshly dipped in a 10-percent parathion solution, showed a gradual decline in fly densities which did not reach control levels until 7 weeks after treatment. This unsatisfactory slow drop in fly densities was due in part to a disruption of normal sanitation practices coincident with the treatment of the dairy. As a result, the pressure of fly production was abnormally high. After the usual practices of manure handling were reestablished, control levels were maintained.

The effect of parathion-impregnated cords on fly populations is depicted most graphically in figure 3. In this dairy (Kn), parathion-treated cords $\frac{3}{16}$ inch in diameter installed the previous year were allowed to remain in the dairy establishment throughout the winter months. In addition, 300 feet of newly treated cord ($\frac{3}{16}$ inch in diameter) was installed in a recently built calf shed. Satisfactory control of flies ensued throughout the following summer. In August, all cords were removed from the barns and immediate increases in fly population levels were noted. In early September,

the same cords were reinstalled and an immediate reduction of fly indexes to control levels was achieved.

The results with Diazinon-treated cords are shown in figure 4. In 1953, the dairy (B) treated with cords ($\frac{3}{16}$ inch in diameter) impregnated in a 10-percent Diazinon solution displayed substantial reductions of the housefly populations, with reduced indexes persisting for 3 to 4 weeks. In 1954, the same dairy treated with cord ($\frac{3}{32}$ inch in diameter) impregnated with a 25-percent Diazinon solution showed immediate reduction of housefly densities to control levels, and these low levels were sustained for 7 weeks. After this period a sharp increase in fly indexes occurred. In mid-August, re-treatment with freshly impregnated cord again resulted in excellent housefly control for a period of 7 weeks.

In figure 5 are shown the comparative housefly population trends in treated and untreated rural areas. After installation of the parathion-treated cords, excellent fly control was obtained for the remainder of the season. In the untreated area, the reduced fly levels were caused by the use of poison baits by individual residents. However, fly population indexes were not lowered to the levels obtained in the zone treated with parathion-impregnated cords.

The results of installation of parathion-

Figure 4. Control of houseflies in dairies with Diazinon-impregnated cords.

solution and air dried for 3 weeks before installation. The second and third dairies (T and Ra, fig. 2) received installations of freshly treated cords impregnated in a 7.5-percent and a 10-percent parathion solution, respectively. The 3-week-old cord installed in dairy C was used as a means of overcoming the 3-week period usually required to bring fly populations to control levels, a lag possibly caused by the repellency to flies of freshly treated cords.

Two areas (2 x 3 miles each) containing approximately 25 houses each were selected for the rural study. In one area, the individual premises were treated with cord impregnated in 7.5-percent parathion solution; the second area served as an untreated check. The 15

premises of highest fly potential in each area were selected for grill index determinations.

Two military dining halls of similar construction and area were selected for study. One dining hall received treatment with cord impregnated in a 7.5-percent parathion solution; the other was used as an untreated check.

Results

The results of the parathion cord treatment in dairies are shown in figure 2. Housefly populations at dairy C, which received a treatment with 7.5-percent parathion-impregnated cord air dried for 3 weeks, were sharply reduced to control levels the first week after treatment,

Figure 2. Control of houseflies in dairies with parathion-treated cords.

Figure 6. Control of houseflies in a military dining hall and kitchen with parathion-impregnated cords.

of the cords for a period of 3 weeks before installation tends to improve their initial efficiency. Assumptions are that during the 3-week air-drying process various fractional impurities of parathion dissipate, leaving a treated cord which apparently is less repellent to the flies. Although the dairy treated with parathion-treated cord, air dried for 3 weeks, gave the highest level of control, it should be noted that the pretreatment indexes at this dairy were much lower than at the other two dairies.

Diazinon-treated cords when impregnated by dipping in a 25-percent solution were extremely effective for periods of 7 weeks. The shorter residual activity of these cords as compared to parathion-treated cords may be compensated for under certain conditions by the lower toxic hazard to mammals.

Chemical evaluation of the parathion concentration in the air of several dairies and kitchens has indicated a level of only 0.02 microgram of parathion per liter of air. Routine checks on the cholinesterase levels of individuals preparing and handling treated cords have shown no significant change in these indexes nor have there been any reports of any toxic effects of the treatment upon the exposed human populations in the dining halls, kitchens, or dairies employed in the studies.

The commercial development of parathion-impregnated gauze in Denmark as reported by Wichmand (14) and its widespread use on

farms in that country have demonstrated that parathion-treated gauze can be used safely and efficiently by the public in fly control. Under similar conditions of commercial preparation, parathion- and Diazinon-impregnated cords offer definite promise as a general fly control measure in the United States. Such cords should be properly identified by poison labels affixed at intervals of 5 feet. In view of the toxic hazards involved in impregnating the treated cord, it is not recommended that such cords be prepared by anyone other than commercial formulators.

Summary

Cotton cords $\frac{3}{32}$ inch in diameter, impregnated in 10-percent and in 7.5-percent parathion-xylene solution, have given seasonal control of insecticide-resistant housefly populations in dairy barns. Cords impregnated by immersion in a 25-percent Diazinon solution yielded 7 weeks' effective control. Cords treated with 7.5-percent parathion solutions provided excellent control of houseflies for more than 10 weeks in rural areas and for 10 weeks in a military dining hall and kitchen. Air samples in dairy barns and in kitchens of rural homes revealed only 0.02 microgram of parathion per liter of air. No significant changes in cholinesterase levels were noted in individuals processing or installing parathion- and Diazinon-treated cords.

treated cord in a military dining hall and kitchen (fig. 6) indicate excellent control of houseflies during the 10-week observation period. Total fly counts in the treated dining hall and kitchen ranged between 1 and 16 flies per inspection, whereas total counts in the untreated dining hall and kitchen ranged between 110 and 260 flies per inspection.

Discussion

The use of smaller cords ($\frac{3}{32}$ inch in diameter rather than $\frac{3}{16}$ inch in diameter) in 1954 was based on the similarity in the control performance of cords of both sizes in previous studies. In addition, the $\frac{3}{32}$ inch in diameter

cord is cheaper and reduces the potential hazard to humans because of the lesser amount of parathion per unit length of cord (75-100 mg. vs. 150-250 mg.). It also permitted an increase in cord dosage per 100 square feet, thereby augmenting the toxic area available for fly contact without increasing the overall amount of parathion within a barn.

In general, the results of the 1954 tests and those of previous studies indicate that parathion is the most effective chemical tested for the treatment of cord for control of *Musca domestica* since it is the only impregnant to date which gives satisfactory control of insecticide-resistant houseflies for extended periods of 2-3 months. Indications are that air drying

Man's Emergence Toward Health

By HENRY VAN ZILE HYDE, M.D.

ONE of the signal honors of public health is an invitation to deliver the annual Winslow lecture. I am fully cognizant of this and deeply appreciative. All of us, I am sure, could tell of acts of friendship that have been extended to us by Professor Winslow and Mrs. Winslow, and we could tell, as well, of the stimulation and inspiration that we have gained from both of them. I had the good fortune to practice medicine in Syracuse, N. Y., a city known throughout public-healthdom as "A City Set on a Hill." I entered practice there shortly after Professor Winslow's book of that title was published, a book that revealed to me an exciting new area of interest and action, an interest which later became my career. So it is with a feeling of gratitude and warmest friendship, which has grown through the years, that I address you in honor of Dr. Winslow.

My title, "Man's Emergence Toward Health," may seem ambitious, but it grows from a feeling that builds up in one, unconsciously and quite inescapably, while traveling about the world in these days with an eye focused on health. We have tended to look at our business of public health as a small business, circumscribed by our own municipal environment, or, perhaps, our State or national environment, but since World War II public health has grown beyond these limits. There is a movement under way in health which constitutes one of

the great facts of our time, a force that is shaping world events now and for the long future. We as public health workers must recognize this force in our own field, understand it, and guide it, for any great force loose in the world today can be used to build freedom or, on the other hand, to build tyranny.

Universal Swing Toward Health

The story of the development of public health in northern Europe and in the United States is known to most of you. It is a story told by the public health historians and particularly well, of course, by Dr. Winslow. As historians and philosophers view the progress of man, some see it as a slow upward crawling interrupted by frequent backward slippings. Others see it as a series of explosions, each related to some new basic discovery such as fire, cultivation, domestication of animals, the discovery of iron, or the harnessing of atomic energy. The development of public health appears to take this latter form, an explosion which, indeed, is modeled on the ultramodern design of the mushroom cloud—in shape but not in effect. The vertical stem of the cloud is the explosion in time—public health history. It is a very, very short history as you know, occurring almost entirely within two, or at the most, three generations of public health leaders.

Short as is the vertical stem of the public health explosion, we are witnessing today the equally dramatic lateral expansion of the mushroom cloud. Prior to World War I, public health activity in great areas of the world, if extant at all, existed mainly for the protection of the colonizing forces, for the governors of men, not for man himself. Today, in contrast,

Dr. Hyde, chief of the Division of International Health, Public Health Service, and United States member on the Executive Board of the World Health Organization, delivered the Winslow lecture at Yale University, March 28, 1955.

Diabetes Control Courses in Boston

Four courses in diabetes control will be given at the Public Health Service Diabetes Field Research and Training Unit, Boston, Mass., for physicians, public health administrators, nurses, dietitians and nutritionists, social workers, health educators, and medical technicians. The courses for 1956 are:

Patient education in diabetes, designed for those concerned with individual and group instruction of persons with diabetes and with the families of these patients, will be given from February 27 to March 2. It is recommended for teams of workers. Membership for this course is limited to 12.

Nursing aspects of a diabetes program, designed for nurses in official and nonofficial health agencies, general and special hospitals and other institutions, clinics, schools, and hospitals, will be given March 19-23. Enrollment is limited to 15.

The clinical and community approach to diabetes will be given April 23-27 and again October 1-5. Planned for professional workers interested in diabetes programs, membership is limited to 20. Priority is given to applications from teams of staff workers from one agency.

Nutritional aspects of a diabetes program, given May 21-25, is arranged for dietitians and nutritionists in public and private health agencies, clinics, hospitals, and other institutions. Membership is limited to 15.

There is no fee for registration or tuition. The classes run from 9:00 a. m. to 4:30 p. m. daily. Part-time or intermittent attendance is not accepted. Application for admission to any one course should be filed as early as possible. Information about hotel accommodations will be sent after application is received. Further inquiries should be addressed to: Diabetes Field Research Training, 639 Huntington Avenue, Boston 15, Mass.

this disease whereas a recent survey following an intensive nationwide campaign showed only 0.03 percent of a sample rural population infected. Under the program presently being conducted in Indonesia, where there are an estimated 20 million persons infected with yaws, the target is 1 million examinations per month expected to reveal 83,000 clinical cases which will be given the required treatment.

The scope of the work that is under way is further attested to by the international program of vaccination against tuberculosis with BCG vaccine. Since 1947, while the experts have continued to debate the exact value of the vaccine, 101 million children, or approximately 10 percent of the world's children under 10 years of age, have been tested for tuberculin sensitivity, and 43 million of the negative reactors have been vaccinated.

Even in the face of such massive accomplishments, the expanding mushroom cloud of the health explosion would have little substance in the absence of a sound basic health structure. The availability of effectively organized and competently staffed national and local health services capable of thoughtful planning and able to reach the people is, of course, the essential ingredient of permanent accomplishment. Mass control of disease is pointless, except as a transient satisfaction, unless there are

services available to maintain the achievement. Therefore, the element of greatest significance in the present movement—that which Dr. Winslow would consider most fundamental—is the widespread establishment of such services.

Organizational progress both centrally and at the community level is being made in many countries. Eight of the governments of the Western Hemisphere have elevated their health departments to the rank of cabinet ministries within the decade. These ministries, as well as the health departments that exist elsewhere, are being manned to an ever-increasing extent by well-trained personnel. During the past 12 years, at which time the Institute of Inter-American Affairs gave the lead in establishing international governmental fellowships, more than 1,700 fellowships have been awarded to Latin American professionals by the institute for study of various phases of public health in the United States. During the years 1947–54 the World Health Organization awarded 4,356 foreign fellowships on a worldwide basis.

The flow of foreign fellows being placed by the Public Health Service under a variety of programs for training in the United States is shown in table 1. This is, of course, additional to the fellowship programs of the private foundations and of governments themselves. In

we see a profound and universal swing toward health for all men who people the world.

Evidence of man's explosive emergence toward health is seen in the current mass attack on communicable disease in the underdeveloped areas, in the widespread development of increasingly competent national health services, in the establishment of extensive networks of rural health centers and in the intensification of international action in the health field.

One of the most impressive and significant phenomena of our times is the mass control of certain diseases, even to the point of eradication in vast areas. The reality of this accomplishment strikes one with great impact on visiting the affected areas of the world: the scope of it is tremendous.

In 1948 the incidence of malaria was estimated at 300 million cases per year. Recently, the World Health Organization has announced that 243 million, or almost one-half of the 552 million people living in malarious areas, are now protected against malaria. In dealing with such figures we are speaking of one-fifth of the population of the entire world. In India 125 million of the 200 million persons exposed to malaria are now protected. Italy, Greece, Iran, Thailand, Ceylon, the Philippines, Formosa, Venezuela, and Brazil are among the countries that have taken similarly important strides in this field. The nations of the Western Hemisphere, not satisfied with mere control of this disease, decided in Santiago, Chile, in October 1954 to act in concert actually to eradicate malaria from the entire hemisphere, and it is anticipated that this astounding feat can be accomplished within the next 8 years. Likewise, a recent World Health Organization malaria conference held in the Philippines resolved that eradication, rather than control, must be the objective in Asia.

On a somewhat lesser scale, yaws, which is a particularly crippling and disfiguring chronic infection, presents a similar example of accomplishment in mass disease control. Within the last 6 years 35 million people have been examined for yaws, and 8 million have been treated. As recently as 1950, 50 percent of the total population of Haiti and an even higher percentage of its rural population suffered from

PHILIPPINES—A nurse from a rural health center visits a barrio under her jurisdiction. Her work and that of others like her is slowly replacing the work of the *herbolarios* and primitive jungle practitioners.

number of countries—either as separate health plans, as in the case of the \$75 million 5-year health plan in Iraq, or as a major segment of a general development plan, as is the case in Iran, India, and Pakistan.

The far-reaching character of the present movement in health is evidenced best by the rapid expansion of networks of urban and rural health centers which are penetrating remote areas and blanketing much of the world. While providing varying degrees of medical care, which they must in the areas in which they operate, they are increasingly providing preventive services with trained auxiliaries assisting the professional personnel. Quite surprisingly, it is not possible to find and present any substantial data on this dramatic development; even the nomenclature is muddy. There is in this a serious gap in our knowledge that needs to be closed. The spotty information that can be found is presented in table 2. Increasingly, such centers are becoming integrated into total community development programs, which encompass services designed to improve agriculture, education, and the total village economic and social structure. At the moment

this desirable trend is conspicuous, particularly in Mexico, Egypt, and India.

International cooperation, as a field of action, presents dramatic evidence of the momentum of the health movement on a world basis. Before World War II there was limited activity in international health carried on by the International Office of Public Health in Paris, the Pan American Sanitary Bureau in this hemisphere, and the League of Nations health section, the work of these organizations being, at that time, restricted almost entirely to the international exchange of epidemiological information.

However, the League of Nations did embark, in a small way but with great vision, on programs for the development of international standards for drugs and biologicals, the improvement of health statistics, the development of standards of human nutrition, and the provision of technical assistance to governments in the development of their own health services. Through its survey and advisory health missions to Greece, China, Bolivia, and other countries, it became the pioneer in the field of international technical assistance which has expanded so greatly in many fields since World War II.

Emergence of WHO

From these origins sprang the World Health Organization. It is not the world equivalent of the health department located in the cellar of the county building. From the standpoint of membership of sovereign nations, the World Health Organization is the largest official international structure ever built by man, with a membership of 80 states as compared with the United Nations, for instance, which has a membership of 60 states. Staffwise, with 1,307 employees, it is the largest agency within the United Nations orbit, except for the United Nations itself. On the world scene, therefore, health is, today, one of the "big shots" of intergovernmental action. This represents explosive progress.

The health budget of the League of Nations never exceeded \$400,000, of which only \$200,000 was contributed by governments. During the interwar period the total annual governmental

several of the countries, such as Brazil, Mexico, Chile, and Lebanon, training is being bolstered by new schools of public health that have been established or, as in the case of the Philippines and India, old ones that have been recently strengthened.

New and essential basic organizational units, such as divisions of public health nursing, environmental sanitation, sanitary engineering, health education, vital statistics, training, planning, and so forth, are being established within health departments and ministries. Twenty-three of thirty-seven of the less highly developed countries, for instance, today have a nurse serving in the ministry of health at the national level as shown below:

Nurse at national level: Brazil, Chile, Colombia, Costa Rica, Dominican Republic, El Salvador, Formosa, Haiti, India, Indonesia, Iraq, Israel, Korea, Lebanon, Liberia, Mexico, Panama, Paraguay, Peru, Philippines, Thailand, Uruguay, Venezuela.

No nurse at national level: Afghanistan, Bolivia, Ecuador, Egypt, Ethiopia, Guatemala, Honduras, Indochina, Iran, Jordan, Libya, Nepal, Nicaragua, Pakistan.

It is of particular significance that the first category includes a number of countries in which women were in deep purdah until very recently. The demonstrated value of nursing has over-ridden the prejudices and attitudes of many ages.

As part of the development of more effective services, there is a movement toward the progressive decentralization and expansion of health administrations, bringing them into closer relationships with the people they are designed to serve. Such movements are particularly conspicuous at the moment in Iran, Iraq, the Philippines, Brazil, and Mexico. Rather extensive formalized plans covering various periods, usually 5 years, are under way in a

Table 2. Rural health centers in certain countries

² Provided for in 1955-56 plan.

effect. It has been clearly demonstrated, however, in the relatively recent era of scientific public health that widespread and oppressive diseases can be controlled in a predictable way. The miracles of immunology and sanitation have been followed by those of DDT and penicillin. These have occurred concurrently with the widespread development of communication and transport, which has spread the message widely.

The extent to which news penetrates to remote places is perhaps not generally understood. The blaring of a public radio in the town square or at the main crossroad has become characteristic in poor and primitive population centers. It is not necessary to be literate, or to be able to afford a radio set or even the day's paper in order to keep in direct touch with world affairs. Further, remote areas are being opened up through the extension of farm-to-market roads and through the routine use of

air transportation. The airplane has knitted together the scattered and isolated towns in such mountainous countries as Honduras and Colombia. President Tubman of Liberia now carries government, for the first time, into the remote bush through personal visits in a light plane. The Indian Health Service of Canada utilizes the airplane to provide regular service in the vast tracts of the north. This new nearness of man to the foci of progress has fed the desire for better health.

Since any desire shared by a significant number of people constitutes a political force, it is apparent that the widespread urge for health manifest today is a highly potent political force demanding action. Its intensity is heightened in countries that have recently attained independence because self-rule is associated in men's minds with a good life. Why, otherwise, fight for it?

THAILAND—Assistant director of a malaria control unit demonstrates mechanism of spray guns.

HAITI—Yaws patients wait for treatment at a clinic.

contribution to international health work, including contributions to the International Office of Public Health in Paris and the Pan American Sanitary Bureau, never reached \$300,000, with the United States, which was not a member of the League, contributing only \$6,000 to the world program and \$60,000 to the hemispheric one each year.

This provides some measure of the extent of governmental interest in health so short a time ago. In contrast, the World Health Organization budget, financed entirely by contributions from governments, is now at the level of \$10 million. In addition, WHO gives leadership and direction to health programs it undertakes jointly with the United Nations Children's Fund and the United Nations Technical Assistance Program. Its total annual resources, direct and indirect, are, therefore, in the neighborhood of \$15 million.

Governments established the World Health Organization because of their recognition of the need for international cooperation and assistance in health, yet, in 1948, when the World Health Organization stepped onto the world stage and offered technical services to governments, there were few takers. Most governments wanted supplies and nothing less tangible. The scene has changed rapidly with the growth of understanding, and today the World Health Organization has technicians in almost every country in the free world. In 1954 alone,

it was engaged in 329 major projects in 75 countries. Its most pressing problem is that of meeting from its available resources the requests that flow in.

The World Health Organization activities represent common action through international pooling of resources and skills. The United States is supplementing these activities by conducting a cooperative international technical assistance program in health, which is administered by the Foreign Operations Administration with the support of the Public Health Service, the universities, and other private agencies. (On July 1, 1955, the Foreign Operations Administration was abolished, and its technical assistance activities taken over by the International Cooperation Administration of the Department of State.) This is the program widely known at one time as point 4, which has a health component operating at a level of \$26 million per year. Taking this into account, the total contribution of the United States to international health work, made directly and through the international agencies, now ranges around \$40 million. This is a far cry from the \$66,000 of only 10 years ago.

The Demand for Better Health

Recognizing that there has been a great acceleration in the tempo of health development, one wonders what the underlying factors are that have brought it about. The fundamental factor is a demand from the masses for better health, growing from the demonstration that health can be obtained at a reasonable cost through techniques now available. The realization that ill health is avoidable has penetrated to the remotest areas, creating a political force of local, national, and international significance.

The demand for health is based fundamentally, of course, on the innate animal desire for relief from pain and suffering and the equally innate instinct to protect one's offspring. Through the milleniums, efforts to modify pain and suffering have been made through sacrifices to many gods, through attempts at avoidance by haruspicy, through incantations and the taking of strange mixtures. None of these efforts had a consistent

here and abroad. The relationship of health to economic development, which has been so clearly set forth by Professor Winslow and dramatized particularly by the modern story of malaria, has attracted the thoughtful attention of those who shape world affairs and has given health work much of its present momentum.

A lesser factor contributing strength to the international movement in health is the fact that protection against exotic disease in the face of modern transportation speeds has required a positive approach rather than the negativism of traditional quarantine. This positive approach has taken the form of international assistance in the control of disease at its source. In his account of Mr. Barr and the innocent introduction of smallpox into the United States, Dr. James S. Simmons has given us in "Public Health in the World Today" a compelling story of the need for this approach.

As contrasted to narrow nationalism, the growing recognition of the world as an essential whole provides the milieu within which health action spreads rapidly and widely without too great reference to artificial boundaries. Inter-relatedness has replaced isolation, and there is a true sense of mutual responsibility for the state of the world at large.

In the free world, this sense of mutual responsibility is not motivated by political or economic opportunism alone. Much deeper and more meaningful forces underlie today's internationalism. The moral concepts that have shaped our own American freedom are known throughout the world and are inspiring today's movements toward freedom. The Declaration of Independence is not solely a United States document but a world platform; Lincoln is not a local figure but a world hero and a universal symbol of faith and hope. We can easily recall how the Atlantic Charter and its four freedoms electrified us only a few years ago. We wish to make good on those promises.

We cannot indeed sidestep moral responsibility for preventing disease because we know, with Thucydides, that "the true author of the subjugation of a people is not so much the immediate agent, as the power which permits it, having the means to prevent it." And we are

the ones who have the means to prevent disease.

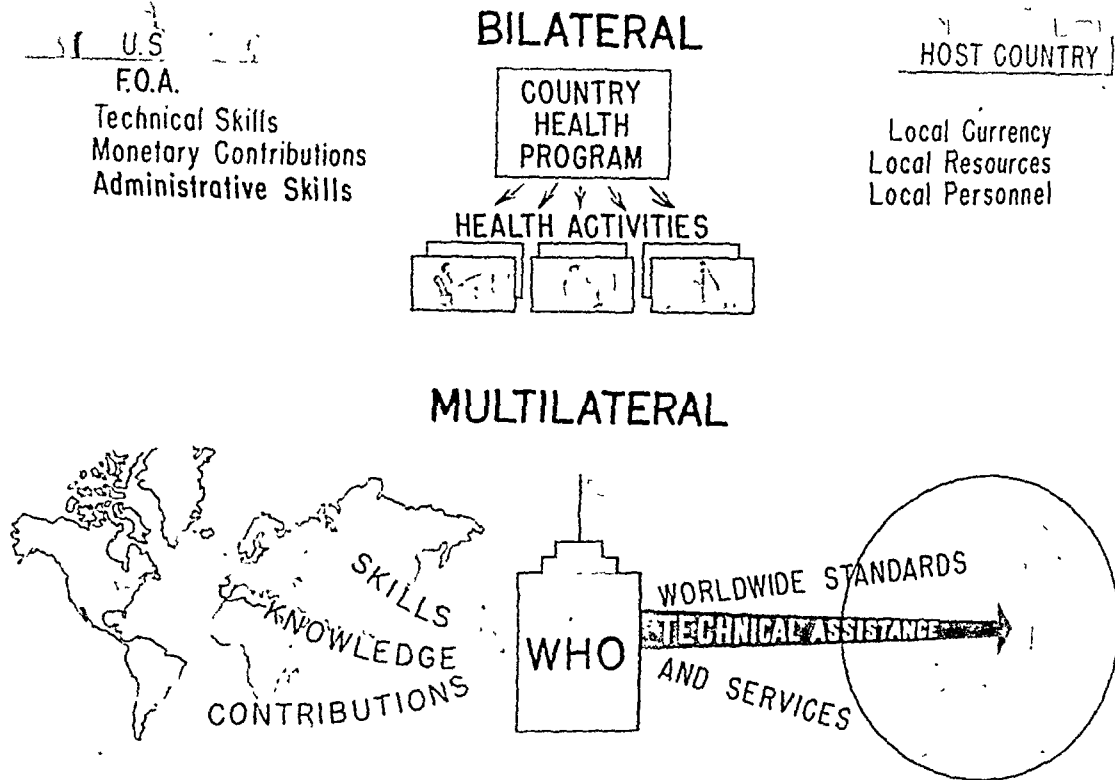

The moral drive underlying international action does not stem solely from political philosophies or from guilt but from a deeper root that underlies philosophy and guilt. It is perhaps a fortunate thing that the power and the wealth and a large measure of the greatly needed technical skills are in the hands of those whose religion drives them to share their substance. The medical missionary is a forerunner in spirit, more than in technique, of the official international programs in health.

Where can we derive more immediate satisfaction of our moral urge than in the field of health, sharing our resources in order to solve the massive immediate human problem touching every man? Freeing man from the burden of disease so that he might have flight of spirit satisfies the requirements of today's moral urge as well as any immediate material goal. Whether programs are labeled health, agriculture, economic development, or technical assistance, the improvement of man's daily life is their goal, and, directly or indirectly, they must bear upon man's health.

All of this is of particular importance to us as workers in public health. We cannot think of peace as a problem solely for the diplomat or the statesman, nor of economic development as a problem for the economist alone. The emergence of man toward health constitutes a fact of our times within our own sphere of responsibility that is very truly affecting the future of mankind. India will never again be what it was yesterday, nor will Brazil, nor Mexico, nor Haiti, nor Indonesia, nor any country in the so-called underdeveloped belt.

We, as professionals in the field of health, have the primary responsibility for assuring that this great force, which is expressing itself with explosive rapidity, is utilized to the fullest extent in the furtherance of freedom and the establishment of peace. It is incumbent upon us not only to recognize it but to understand it much more deeply than we do today. As in the case of any great force, it can be used well or badly for good or for evil. Its proper use is our particular and inescapable world responsibility. May we discharge it wisely and for the betterment of all mankind.

PATTERN OF COOPERATION

Such different men as Magsaysay, Nehru, U Nu, Mohammed Ali, Soekarno, and Kotelawala, who in common are leaders in newly independent countries, have initiated extensive national activity in health in a conscious effort to satisfy this expectation. Others, new in power, in countries with a long tradition of independence, such as Pibul Songgram in Thailand and Paz Estenssoro in Bolivia, have likewise stepped up health activities with a view to achieving stability and combating subversion. The communists utilize this same force in order to accomplish their ends. John Ridley, who accompanied Clement Attlee on his visit to Red China, has reported at some length in the *New York Times Magazine* (August 29, 1954) on the manner in which health is being employed to strengthen the hand of the present government there.

Internationally, the same political factor is at work. Here it is a matter of the cumulative force of the health demands of the total of the world's population. As the antipodal forces of

freedom and tyranny clash on the world scene, each is trying to gain the adherence of the masses and using either health promises or performance as one means of doing so. We, for our part, have promoted and supported health measures through the World Health Organization, the Pan American Sanitary Bureau, the United Nations Children's Fund, the International Cooperation Administration, and the Colombo Plan for Cooperative Economic Development in South and Southeast Asia. On the other side, it has been largely a matter of false promises.

It is a generally accepted tenet of modern political philosophy that peace can survive only in the presence of economic growth and stability. There is increasing acceptance of the additional fact that a sound economy cannot be built upon a sick population. Professor Winslow has made a major contribution to this area of thought in his monograph on "The Cost of Sickness and the Price of Health," which was published in 1951 by the World Health Organization, and which has had wide influence

eyes, the tone of their voice when they mention their father—these are not statistics. They transcend cold, hard facts and figures.

The young man who didn't complete his schooling because, a generation ago, his father died of tuberculosis has finally worked up to a decent job, has married and had his first boy, and is now told that he, too, has tuberculosis. But, it is early and minimal, because it was picked up by a mass survey before he became ill. A fine hospital with excellent medical care is freely available to him. A public health nurse will help his physician check his family and will help carry out a home care regimen prescribed by his physician after a shortened hospital stay. We know, and he knows, that his chances of returning to his family and his job within a reasonable length of time are excellent.

These are the human values we are dealing with day in and day out. Let us not move so far away from them that we, or any one else, will be allowed to think of public health only in terms of statistics or dollars.

Applied Principles

The principles we are applying in a stepped-up program of health protection for Pennsylvania are many.

First, we accept the fact that optimum communitywide prevention of disease is not a one-man or a one-agency affair. Three links are needed to forge the chain, each one equally vital: the individual, who must be given the knowledge of, and willingness to accept, what modern medicine can offer him; the private physician, the first line of defense against many diseases, who should provide community leadership in all health programs; and the health agencies, official and voluntary, which can do those things not possible individually but effective on a group or community basis. It has been used so much that I hesitate to label public health a "team" affair. But, with the complexity of our social and industrial structure and with the variety and costliness of health protective techniques now available, it most certainly requires the best efforts of all—working together as closely as we can—to do the most nearly complete job.

Second, we have accepted the increasingly important role played by health education in today's public health practice. Health education stands in the same paramount position now as sanitation did 50 years ago. It presents our best weapon against the chronic diseases now most prevalent, just as sanitary measures provide a continuing bulwark against the gastrointestinal diseases.

Our task is not simple, for information is not enough. We must learn how to break down "sins" which beset us all—lethargy, rationalization, and misinformation. Probably no area of discussion, not even the weather, has been so long and thoroughly explored as our physical and emotional ills. Yet we have only to consider the folklore which has been built up around one disease, poliomyelitis, to highlight our difficulty. *Much misinformation must be dispelled, much wishful thinking replaced by openmindedness, before we can begin to arouse folks from their complacency and stimulate useful action. This will take time, training, and tenacity.*

Third, we accept the proposition now repeatedly proved across the land that health services as nearly indigenous as possible are the most effective. Pennsylvania has, and always should have, broad responsibilities to see that the health of its people is protected. It will probably always be far more economical and efficient to have a central staff of experts in the various health fields to prepare standards and devise general programs.

But only as counties and health districts begin to participate in both supporting and providing the services they need to protect their health will those services be best tailored to each community's needs and be best accepted by its residents.

Only two counties have used the 1951 permissive legislation to establish local health departments. Many more are seriously exploring the possibility. What do county departments of health offer these areas now considering this extension of health protection? They offer more local determination of service priorities based on greater sensitivity to local needs; qualified medical leadership in public health, which in turn means closer coordination with

Public Health in Pennsylvania

By BERWYN F. MATTISON, M.D.

OUR changing attack on disease is necessitated by changing community disease patterns. To provide new and extended forms of health protection for the people of Pennsylvania, we have asked for support of services of proved efficacy and for limited demonstrations to provide effective health protection techniques where none are now available. Without that support, the people will die needlessly.

A Purchasable Commodity

It has been said that "public health is purchasable," and that statement is still true. If those who might be tempted to "economize" on health could but know the human details of the resultant personal misery, they would hesitate no longer. This understanding is no matter for statistics. Even words are inadequate!

To appreciate the real value of what we do in public health one must experience the moments of anguish, as so many physicians and nurses present today have, when a mother is told that her tiny daughter, born a few hours or days prematurely, has not survived—and know, within his heart, that with very special care,

she might have lived. Or, one must have had the responsibility of telling parents that their apparently healthy boy has epilepsy and feel keenly that much could be done for him that may never be done.

I have seen an otherwise attractive little 9-year-old girl hiding behind a packing box and peering wistfully out at other children because her unrepaired harelip was a thing of laughter and ridicule among them. Yet, Pennsylvania has one of the best programs in the Nation for that kind of care. I have looked into the eyes of a still feverish child who was running and playing a week ago and evaded the answer to her unspoken question as she tried to move a leg made limp by poliomyelitis and wondered if our present local health services are geared to assure every child in the State the new protection available.

How many of us have cared for cancer patients—heard them tell of their families and their plans for the future—when we knew full well that, through lack of information, or diagnostic facilities, or willingness to accept early treatment, they had already traded a probable cure for certain tragedy? Not only statistics but a sense of personal values should indicate universal support for our programs.

The estimated number of Pennsylvanians suffering from chronic alcoholism is staggering. The dollar loss to industry, year after year, is appalling. But the real enormity of the problem only hits us when we think of our friend and neighbor, Joe Doaks, who had a good job, a home, and a happy marriage with two fine children. Before help was provided, he had lost his job, his home, and the respect of his wife and children. The look in those children's

Dr. Mattison, secretary of health of the Commonwealth of Pennsylvania, presented this paper at Pennsylvania's Fourth Annual Health Conference, held August 16, 1955, at University Park, Pa. In Pennsylvania, the health conference pattern provides for full participation of four autonomous groups: the Pennsylvania Department of Health, the Health Council, the Medical Society, and the Public Health Association.

Epidemiological Tests of Theories on Lung Cancer Etiology

By WILLIAM HAENSZEL

QUESTIONS on the etiologies of lung cancer cannot be resolved by a single, decisive experiment or set of observations, and a single study is not the natural unit for discussing the epidemiology of this disease. The major concern must be with the interrelationships of findings and their collation to see whether a chain of evidence stronger than any single component part can be forged. Information on a proposed etiology cannot be assessed without relating it to both positive and negative findings on alternate possibilities, drawn from animal experimentation and other laboratory work as well as from epidemiological studies. Also, with a subject under such active scrutiny as lung cancer, it is difficult to attempt to divorce facts already established from interpretations which may either be stated explicitly or merely be implied by investigators through their choice of specific studies to be pursued. Under these conditions, a better perspective on epidemiological issues in lung cancer studies may be gained by viewing them in the perspective of possible future work. Since interrelationships of individual findings are the main concern, this paper

deals more with the ideas underlying a set of studies than with the tactical details of any single study.

Increase in Lung Cancer

If no real increase in lung cancer existed, all associations between lung cancer and exposure to atmospheric pollution, cigarette smoking, or other exogenous agents recently introduced into the environment would be suspect as not pointing to possible etiological relationships. A few persons still maintain that the recorded increase in lung cancer incidence and mortality is fictitious and has resulted from improved diagnosis (1), but this is no longer a popular position (2). Among the reasons for accepting a real increase in lung cancer mortality are the sex differences in rate of increase and the magnitude of the current, continuing increase (3).

One purpose for inquiries on the increase in risk would be to provide more precise quantitative estimates than are now available from mortality data which may later prove useful for reconciliation with numerical measures of exposure to suspected agents. For this reason, anyone proposing to study the effect of possible misdiagnosis of lung cancer as tuberculosis (4) or some other cause should relate these effects to data produced by the death registration system. Samples of deaths from lung cancer and other causes taken from vital statistics sources could be compared with autopsy protocols and other diagnostic evidence. Evaluation of the

Mr. Haenszel is head of the Biometry Section, Biometry and Epidemiology Branch, National Cancer Institute, Public Health Service. He presented this paper at a joint session of the Biometrics Society and the Institute of Mathematical Statistics, Chapel Hill, N. C., April 23, 1955

the clinical practitioners and increased interest on their part in preventive medicine; a broader tax base for the support of health services; and more readily available local services, whether they be nursing, immunization, sanitation, or health education.

As county departments spread across the State, many of the direct service functions now provided out of Harrisburg can be cut down proportionately. Supervision and correlation will, of course, be continued through district and regional offices.

Fourth, we accept the need for continually evaluating our programs. This is not easy, and we are inclined to give the concept lipservice rather than to work out real evaluations. There are at least three levels on which a program can be tested for its worth: the degree to which it meets a short-range, immediate objective such as reduction in complaints after correction of an overflowing septic tank; or the degree to which the program complies with established standards of acceptable performance such as the percentage of employees in a department having permanent merit system status; or finally, the degree to which a program can be associated in a cause and effect relationship with decreased morbidity and mortality rates. But whether our program tests are at the proximate, intermediate, or ultimate levels, some tests must be

made, and year by year they must be improved. One of the immediate tests we might apply is to check our services against the health indexes of the people served.

We can observe vast differences in these health indexes. For example, our best 3 cities, as far as infant deaths are concerned, have an average infant death rate of 3.1 per 1,000 live births, but our poorest 3 cities have an average death rate of 14.6. This means that for every 15 baby deaths in one kind of community the other community has only 3. Are we putting in proportionately greater efforts to reduce the latter toll? Our best 5 cities have an average tuberculosis death rate of 2.6 per 100,000 population, but in our worst 5 cities we have an average rate of 20.3. So, for every 20 tuberculosis deaths in one kind of community there are less than 3 in the other. Our intensified efforts should be focused on the area with the greater need.

With these principles in mind, teamwork, health education, local autonomy, and evaluation; with adequate financial support from our appropriating bodies; and with the continued selfless dedication to the cause of better community health on the part of every one of us, we will together decrease each year the number of those among us who have been dying needlessly.

Mental Health Admissions

There were more than twice as many first admissions as discharges at public mental hospitals in 1954, according to the National Institute of Mental Health, Public Health Service.

New cases numbered 12,485, or 8 per 100,000 population, while 5,815 patients were discharged and 1,026 readmitted. The average daily patient load, including epileptics as well as mental cases, was 138,595, with 109,931 classed as mental defectives. The range of expenditures for patient care varied considerably among the States, but the average cost per patient-year was \$1,039. Of the 157,770 patients on the hospital books at the end of the year, 139,977 were listed as in residence.

Data compiled by the National Institute of Mental Health for 1955 will appear in the forthcoming issue of *Public Health Reports*.

such as industrial and heating plant wastes and motor vehicle exhausts.

Atmospheric Pollutants

To date, atmospheric pollution theories have not been well documented by demonstrations of excess risk among workers with heavy exposures to common atmospheric pollutants such as may exist in railroad yards, oil refineries, and congested urban areas. With the advent of group insurance and pension plans, the methodological problems of such inquiries have become much simpler. Several cohorts can be located for study. The National Cancer Institute is following a group of 1,100,000 railroad employees who have been in the industry 10 years or longer, including station, office, yard, and shop employees, as well as train crews. Rather detailed occupational histories are available and, with the accumulation of mortality data over several years, such specific points as the effects of dieselization, prolonged exposure to smoke in railroad tunnels, and metal dust exposures in shops may be looked into. The important feature is that work histories and exposures be specified in some detail. Significant effects may be diluted and overlooked by considering only gross company or industry experience.

The widespread use of petroleum products makes it very desirable to gather data on workers in that industry. Some medical departments of the major oil companies have staffs well equipped to undertake such studies. The major problem here, as elsewhere, is to secure access to company records and to rearrange data organized to meet other administrative needs. In areas where petroleum operations are concentrated, data might be collected on a geographic rather than an industrywide basis. At least one study is under way in Oklahoma which may yield some information on lung cancer risks among oil industry employees.

Those advancing atmospheric carcinogen theories have pointed to the sizable urban-rural differentials in lung cancer risk (14), although some further assumptions are required to reconcile this hypothesis with the great excess risk observed among males. The presence of carcinogenic substances in urban atmospheres has been repeatedly demonstrated by experi-

ments with mice (15, 16). Further epidemiological work has been hampered by the inability to classify individuals in the general population quantitatively with respect to atmospheric exposures. Meaningful histories are hard to collect, and in mobile populations, problems of classification by residence histories become complex. When leads on specific types of atmospheric pollutants are obtained from studies of special situations, the way may then be opened for return to the problem of reclassifying the general population with respect to special exposures with greater chance for success.

Smoking of Tobacco

Although at least 14 retrospective clinical studies (17) have reported on the association of smoking and lung cancer, these studies have been criticized on a variety of technical grounds. The objections advanced cover such points as interviewer bias (interviewers in some studies knew the identity of lung cancer patients and controls at the time of interview), and bias arising from selection factors associated with hospital admission (in most studies only hospitalized lung cancer patients were interviewed). However, the objection based on knowledge of the identity of patients and controls ignores the evidence of Doll and Hill (18) that males erroneously interviewed as lung cancer cases, as established by later events, showed smoking histories characteristic of the control rather than of the lung cancer series. Because of possible selection factors involved in taking up the smoking habit, some feel that the tobacco-lung cancer associations reflect associations with other common, but still unidentified factors.

The present data on associations between smoking and lung cancer are the most extensive and afford the most opportunities for discussing additional studies. For orientation, the type of evidence now on hand may be compared with the epidemiological findings for cholera, pellagra, and dental caries, all diseases in which animal experimentation played a minor role, at least in the early phases of the investigation (19-25).

On review, the basic core of associations on smoking and lung cancer must appear as impressive as any produced in these other investi-

two sources of error in official statistics, (a) deaths from other causes erroneously recorded as lung cancer and (b) lung cancer deaths attributed to other causes, would be rendered difficult by the selective character of autopsy statistics. However, the effort should be made. A useful minimum objective would be to determine how many lung cancer cases remain undiagnosed at present. Farber reported that in a series of 1,070 morphologically proved cases of bronchogenic carcinoma, 61 percent were not positively diagnosed prior to autopsy (5). Undoubtedly, many of these deaths were not recorded as lung cancer on the death certificate.

Environmental Agents

The working hypothesis for most investigators has been that the probable causes of lung cancer are to be found among environmental agents (2). The association of the high prevalence of cancers for several other sites, particularly the mouth, with specific customs found only in certain parts of the world strengthens the belief that direct contact with known or suspected carcinogens may be involved (6). On the assumption that agents with opportunity for direct contact with lung tissue are the most likely candidates, efforts to establish etiological relationships between lung cancer and environmental agents have been directed into three main areas: (a) airborne agents encountered in special occupations; (b) atmospheric pollutants, particularly those resulting from combustion of hydrocarbons; and (c) smoking of tobacco.

To assert that an agent is etiological related to lung cancer simply implies that its removal from a defined population will result ultimately in a marked reduction of lung cancer. The population must be defined in a manner which safeguards against an effect being produced merely by the process of selection and classification. The concept does not require detailed specification of a mechanism producing the effect. Goldberger's finding that pellagra may be prevented by diet was no less valid because subsequent work led to the identification of the vitamin B complex and, finally, to nicotinic acid as the effective agent. This statement does not imply that ideas on mechanisms

are not helpful; to the contrary, they may suggest situations in which data can be collected and tested.

Occupational Carcinogens

There is general agreement on the etiological significance of several occupational exposures, and such findings have been important in establishing the principle of multiple etiologies for lung cancer. Long-term observations of closed populations have convinced most people that the Schneeberg and Joachimsthal miners (7, 8) and certain groups of chromate workers (9, 10) were subjected, by virtue of their occupations, to excessive lung cancer risks. The evidence on chromate workers is purely epidemiological, not confirmed by animal experimentation, and was first suspected on the basis of clinical observations. Although many investigators have deduced from the Schneeberg and Joachimsthal observations that radiations emitted from radon were responsible, Lorenz felt that the case had not been firmly established and that other possibilities, such as dust pneumoconiosis, had not been conclusively ruled out (11).

Excess lung cancer risks detected by examination of occupational mortality data, such as data on workers employed in the preparation of coal tar products and producer gas (12), have also been generally accepted as reflecting an etiological relationship between lung cancer and some suspected carcinogenic agent in these products. Nor is there any great disposition to question the status of agents detected by clinical observations and retrospective studies of agents such as arsenic dust, nickel carbonyl, asbestos dust, and coke oven fumes (13). When the study results are reviewed to pick up occupational exposures which appear repeatedly, the danger of being misled by a highly unusual result in a single study is minimized. Additional occupational risks will no doubt be demonstrated in the future. However, because of the small numbers of workers exposed, the further denumeration of very restricted types of risks will not be crucial in working out the epidemiological details of lung cancer. This statement would not apply to the common and widespread agents contributing to atmospheric pollution, including hydrocarbon combustion products

such as industrial and heating plant wastes and motor vehicle exhausts.

Atmospheric Pollutants

To date, atmospheric pollution theories have not been well documented by demonstrations of excess risk among workers with heavy exposures to common atmospheric pollutants such as may exist in railroad yards, oil refineries, and congested urban areas. With the advent of group insurance and pension plans, the methodological problems of such inquiries have become much simpler. Several cohorts can be located for study. The National Cancer Institute is following a group of 1,100,000 railroad employees who have been in the industry 10 years or longer, including station, office, yard, and shop employees, as well as train crews. Rather detailed occupational histories are available and, with the accumulation of mortality data over several years, such specific points as the effects of dieselization, prolonged exposure to smoke in railroad tunnels, and metal dust exposures in shops may be looked into. The important feature is that work histories and exposures be specified in some detail. Significant effects may be diluted and overlooked by considering only gross company or industry experience.

The widespread use of petroleum products makes it very desirable to gather data on workers in that industry. Some medical departments of the major oil companies have staffs well equipped to undertake such studies. The major problem here, as elsewhere, is to secure access to company records and to rearrange data organized to meet other administrative needs. In areas where petroleum operations are concentrated, data might be collected on a geographic rather than an industrywide basis. At least one study is under way in Oklahoma which may yield some information on lung cancer risks among oil industry employees.

Those advancing atmospheric carcinogen theories have pointed to the sizable urban-rural differentials in lung cancer risk (14), although some further assumptions are required to reconcile this hypothesis with the great excess risk observed among males. The presence of carcinogenic substances in urban atmospheres has been repeatedly demonstrated by experi-

ments with mice (15, 16). Further epidemiological work has been hampered by the inability to classify individuals in the general population quantitatively with respect to atmospheric exposures. Meaningful histories are hard to collect, and in mobile populations, problems of classification by residence histories become complex. When leads on specific types of atmospheric pollutants are obtained from studies of special situations, the way may then be opened for return to the problem of reclassifying the general population with respect to special exposures with greater chance for success.

Smoking of Tobacco

Although at least 14 retrospective clinical studies (17) have reported on the association of smoking and lung cancer, these studies have been criticized on a variety of technical grounds. The objections advanced cover such points as interviewer bias (interviewers in some studies knew the identity of lung cancer patients and controls at the time of interview), and bias arising from selection factors associated with hospital admission (in most studies only hospitalized lung cancer patients were interviewed). However, the objection based on knowledge of the identity of patients and controls ignores the evidence of Doll and Hill (18) that males erroneously interviewed as lung cancer cases, as established by later events, showed smoking histories characteristic of the control rather than of the lung cancer series. Because of possible selection factors involved in taking up the smoking habit, some feel that the tobacco-lung cancer associations reflect associations with other common, but still unidentified factors.

The present data on associations between smoking and lung cancer are the most extensive and afford the most opportunities for discussing additional studies. For orientation, the type of evidence now on hand may be compared with the epidemiological findings for cholera, pellagra, and dental caries, all diseases in which animal experimentation played a minor role, at least in the early phases of the investigation (19-25).

On review, the basic core of associations on smoking and lung cancer must appear as impressive as any produced in these other investi-

gations. However, lung cancer does not present the features of geographic localization characteristic for cholera, pellagra, and the absence of dental caries, which made it possible to elaborate in a rather straightforward manner the basic associations with water supplies suspected of contamination (cholera), diet (pellagra), and fluoridated water (dental caries) with corroborative detail and combinations of isolated special situations. Such detail is helpful in ruling out some association as not significant etiologically; in this manner, for example, the associations between cholera and altitude (within London) and between pellagra and mill village occupations could be discarded as not significant. For lung cancer, there are as yet no counterparts, for example, to the cholera patient in an isolated rural area who regularly sent for water from the famous Broad Street pump (19); to the absence of pellagra among doctors, nurses, and attendants in mental institutions, although the disease was common among patients; to the peculiar age distribution for pellagra in a children's institution where the disease was limited to children between the ages of 6 and 12; to differential attack rates for dental caries by gradations of exposure to fluoridated supplies among natives and immigrants; and to the sequence of dental events following shifts in the source of a community water supply. Collection of such details generally results from the study of populations. This is one of the reasons why forward studies on lung cancer among defined population cohorts are so important.

Furthermore, the epidemiological models for cholera, pellagra, and dental caries have been put to the test in the successful application of control measures. For pellagra, only the addition of meat and milk to the diet was involved (26). Fluoridation effects could be observed under controlled conditions because of the happy accident of public water supplies; if private wells were the only source of water, the problem would have been complicated by self-selection of families fluoridating their own supplies. The test of Snow's conclusions on cholera (19), which required implementation through administrative decisions on methods for control of public water supplies, occurred

much later, more than 10 years after he had formulated them.

The right combinations of circumstances to permit such straightforward tests of most of the proposed lung cancer etiologies are not present now. Thus, the immediate lines for further work on the nature and meaning of the smoking lung cancer associations are to develop reasonable facsimiles to tests by control measures and to assemble supporting, corroborative detail from population studies, not overlooking any negative evidence which may appear.

Substitutes for Direct Tests

As a substitute for a direct test by control measures of the smoking-lung cancer model one may look for groups in which smoking is either proscribed for religious reasons or does not otherwise form part of the cultural pattern.

Two of the four basic study elements required are at hand: data on the distribution of smoking habits in the United States population (collected as part of the Current Population Survey for February 1955), and data on lung cancer mortality (from publications of vital statistics offices). The major problems would be to secure the cooperation of the groups selected and to develop procedures to obtain the counterparts of these data for their memberships. To avoid artifacts which might be introduced by classification procedures, the primary test must be whether the overall lung cancer mortality in the group studied was markedly less than for an appropriate segment of the population of the United States and commensurate with differences in the smoking patterns. To this, other refinements may be added, such as observing whether mortality differences between the study and control populations disappear when specific comparisons are made by amount of tobacco smoked.

The limited number of countries which can provide reliable diagnostic data on causes of illness and death has discouraged similar studies of groups abroad which have unusual smoking patterns. However, special study situations may be encountered. One illustration is cited, without judgment as to its intrinsic merit. The director of the Hadassah medical organization recently reported the absence of a single case

of lung cancer among Yemenite Jews in Israel during the past 15 years, and he further observed that they did not smoke cigarettes but used a form of Oriental water pipe (27). Israel is a country with western standards of medical care and this lead may be worth pursuing. In these matters, the importance of reviewing the primary sources of population, morbidity, and mortality data should be stressed.

Other clues may lead indirectly to population groups with unusual smoking histories. For example, Steiner (6), on the basis of necropsy evidence in Los Angeles, has found a possible exception among Mexicans to the usual sex ratio for lung cancer; the proportion of Mexican women with lung cancer at autopsy approaches the proportion for Mexican men. This suggests the need for further studies among Mexicans to confirm the facts and to uncover possible reasons for the aberrant sex ratio for lung cancer. This might conceivably lead to the finding of a group of unusually heavy smokers among women, a useful contrast to the experience of abstainers.

Corroborative Details

Additional details on the nature of the smoking-lung cancer relationship should be assembled from large-scale forward studies. These possibilities were obviously in the minds of those who planned the American Cancer Society and the National Cancer Institute-Veterans Administration studies. Both study groups consist mainly of men between the ages of 50 and 69, the ages of highest lung cancer incidence.

One approach is to expand the evidence on the nature of the association by detailed cross-classification. Epidemiologists have long accepted the principle that the etiological significance of an association is enhanced if it can be shown to persist within a variety of sub-universes. The National Cancer Institute-Veterans Administration cohort can be subdivided with respect to occupation and industry. By lengthening the observation period to several years, further tests can be applied in both studies, including checks on the consistency of regression relationships between lung cancer mortality and amounts of tobacco smoked for

several occupational groups and for urban and rural residents.

Additional tests can be pursued by relating age at death to "age started smoking" to see if any consistent pattern emerges.

Studies Among Women

Unfortunately for study purposes, the spread of "age started smoking" is not too great among men, and it may be hard to assemble sizable cohorts for the more unusual combinations of year of birth and "age started smoking." Women would be more promising subjects, since women of all ages began smoking in large numbers during the 1930 decade, and duration of smoking by women is not so closely tied to chronological age. For this reason, more prospective and retrospective studies on smoking and lung cancer among women would be rewarding. In addition to the one series of studies on smoking among women reported by Doll and Hill (28), two retrospective studies are known to be under way. The relative rarity of lung cancer among women imposes severe study handicaps and has undoubtedly deterred other efforts.

Potential cohorts for followup would include employed women covered by group life insurance policies. To minimize turnover and loss to observation it would be desirable to restrict the cohort to employees with several years' service.

Studies of lung cancer among women should establish what part, if any, of the sex differential in lung cancer mortality (or incidence) disappears when comparisons are made specific for smoking class. The fragmentary Doll-Hill data suggest that a good part, but not all, of the sex differential may be accounted for in this manner.

Indirect Checks

Retrospective and prospective studies may be viewed as efforts to secure etiologically meaningful data, which official vital statistics sources cannot provide, since they are limited to classification by standard demographic variables. There is another transitional bridge by which vital statistics data on lung cancer deaths can

be utilized. By taking information on smoking patterns in the general population (collected in Current Population Survey for February 1955) and applying to them the data on absolute and relative lung cancer risks by smoking class as reported in the preliminary results of the American Cancer Society study (29) and in several retrospective studies (30), the "expected" distribution of lung cancer deaths can be computed by sex, urban or rural residence, geographic region, and broad occupational groups, on the assumption that risks by smoking class in the groups studied hold also in the total population. Comparison of the observed and "expected" numbers of deaths would then show how much of the prevailing variation in lung cancer mortality can be accounted for by considering smoking histories. In this manner, some useful consistency checks on the smoking-lung cancer model would be provided.

Such consistency checks need not be confined to smoking histories. The Current Population Survey material illustrates an economically feasible means for remedying some deficiencies in standard population classifications. Although many investigators have expressed the need for procuring information on the population distribution of characteristics under study, they have often been deterred by the cost. Probability sampling methods for gathering such data can provide a powerful tool to the epidemiologist.

Other Possible Factors

Turning from suspected environmental agents with properties which permit direct contact with lung tissue, several possible causes of lung cancer remain. There is the class of environmental agents which do not come in direct contact with lung tissue. Closely related would be possible tissue changes induced by virus and other infectious agents. Constitutional susceptibility might also be considered. If some persons have a predisposition to attacks on lung tissue by some morbid process, the rise in lung cancer might be due to the suppression of "competitive" respiratory causes, such as tuberculosis and pneumonia. Finally, there is the possibility of the association of smoking with other physical, psychological, and emo-

tional factors which may be engendered by the processes influencing persons to take up smoking.

In dealing with lung cancer, where prospects for tests of etiological relationships by trial of control measures are remote, other hypotheses, however unlikely, and the collection of evidence to support or discredit them should be encouraged. The pursuit of other lines of investigation will be useful. If results are positive, another effect of lung cancer will have been discovered; if negative, they will buttress the interpretations applied to effects already known.

Gilliam, in a general discussion of chronic disease epidemiology, alluded briefly to a variety of items investigated by him in a study of lung cancer patients and controls, using the retrospective, case-history method (31). These items ranged from color of eyes and use of dentures to histories of illnesses and use of general anesthetics. As he hastens to say, such individual findings cannot be used for any generalizations. However, it may be worth while to inquire systematically into other findings collected but never deemed worthy of report. Several of the other early retrospective studies were "shotgun" inquiries and collected information on a variety of suspected agents and exposures. Collectively, these results might prove useful for testing and discriminating between hypotheses and the planning of further studies.

Several studies exploring characteristics differentiating smokers and nonsmokers may be expected. The question of differences between the two groups arises because smokers select themselves; smoking is not a *treatment* which can be studied experimentally by randomized application to a population. There is a wide range of possibilities for retrospective studies on the physical, psychological, and emotional attributes of smokers and nonsmokers. The demonstration of an item as being associated with smoking history is essentially a screening device. The further test is whether the item, when applied to a population, produces differences in lung cancer risks equal in magnitude to those yielded by smoking history classifications (if smoking history is uncontrolled), or whether an effect is observed when smoking history is controlled by classification.

Association With Other Illnesses

Some theories on the subsequent increased risk of lung cancer among persons with histories of respiratory illnesses such as influenza, pneumonia, bronchitis, and tuberculosis, based usually on clinical and pathological impressions, have been reviewed by Doll (32), who continues on to point out some observations inconsistent with these theories. No associations of lung cancer with the presence or absence of an antecedent illness have yet been established by observations on populations through the use of retrospective or prospective studies. Retrospective studies are handicapped in this field, because patients with lung cancer and other respiratory disorders apparently recall previous respiratory ailments more readily than do other persons. There are some possibilities for forward studies on cohorts known to have recovered from specific illnesses, free from the "recall" bias in the retrospective approach, which may be exploited. For example, records can be assembled of World War I veterans who had influenza and/or pneumonia in 1918. These veterans can be traced forward in time to determine their lung cancer mortality experience. (A study of British veterans (40) has been published recently.) From civilian life, one could draw on recovered pneumonia cases reported to health departments in the 1930 decade, when these agencies had active programs based on pneumococcus typing and distribution of serum.

If excess lung cancer mortality among such groups were demonstrated, this would not necessarily be a result of effects of antecedent illnesses. If constitutional predisposition of lung tissue were a factor, the rise in lung cancer mortality might be due to the suppression of tuberculosis and pneumonia as causes of death. If a genetic basis for constitutional predisposition to lung cancer were postulated, other tests could be devised. One approach would be to assemble lists of relatives of diagnosed cases of lung cancer for followup to determine lung cancer mortality. Lists of familial contacts could be assembled from records maintained in tuberculosis control programs. Investigations of this character might be undertaken more readily in some European countries, where pop-

ulation mobility is low and more comprehensive population record systems exist.

Retrospective and Forward Studies

The preceding sections have emphasized the wide range of possibilities for the use of retrospective and forward study techniques. Retrospective, case-history studies use as their point of departure diagnosed cases of a disease and matched controls and compare antecedent events in their previous histories. Prospective, or forward, studies start with the assembly at a fixed point in time of defined cohorts classified with respect to certain attributes, trace them forward in time, and note events occurring subsequently.

Perhaps the major criticism of retrospective studies for lung cancer has been that diagnosed cases have generally been drawn from hospital populations. Positive association between two diseases, not present in the general population, may be produced when hospital admissions alone are studied, because persons with a combination of complaints are more likely to require hospital treatment (33, 34). Smoking is not an illness, and for lung cancer it is difficult to see how the smoking history could have any influence on hospital admission. Lung cancer is a serious disease normally requiring hospitalization, and roughly four-fifths of all diagnosed cases are hospitalized (35). The proportion is even higher when microscopically confirmed cases alone are considered. There would have to be extraordinary differences in smoking histories between hospitalized and nonhospitalized patients and controls to upset inferences drawn from hospitalized cases (36). So far, the results of forward population studies on excess lung cancer risks among smokers as compared to nonsmokers have agreed in general with those of the retrospective studies. This suggests that biases entering into the selection of hospitalized cases and controls studied retrospectively are probably not the source of the associations noted.

The fundamental assumption underlying retrospective studies and the estimation therefrom of differences in risks between population groups is that the diagnosed cases and controls each be representative of the universe chosen

for investigation. Although there are precautions which can be taken in devising a sampling plan, this representative property cannot be guaranteed merely from internal examination of a single set of data. One must be guided on this point by the comparison of results from several studies and judgment as to the possible biases operating in any setting.

Forward population studies have been questioned on the grounds that the cohorts have not been selected by probability sampling methods and that individual study results cannot be generalized to the total population. The expense involved in tracing cohorts drawn from the general population by probability sampling methods would be great and most investigators have been forced to look for populations followed routinely for other purposes, such as persons covered by employment or insurance benefits.

The criticisms of unrepresentative sampling would appear to disregard the experience available from actuarial sources. There are two common types of insurance: "ordinary" policies, which require applicants to pass a physical examination, and "industrial" policies, which undergo some underwriting selection but require no physical examination. Policyholders would scarcely meet the usual criteria for representative samples. The Metropolitan Life Insurance Co. has published extensive data on the mortality experience of their industrial policyholders and finds rather close agreement with the mortality experience of the general population, after appropriate adjustments for age, sex, and race composition (37). Data drawn from actuarial experience and reported in such sources as *Length of Life* (38) and *The Statistical Bulletin*, a monthly publication of the Metropolitan Life Insurance Co., indicate that the relative patterns of mortality with respect to cause, age, sex, race, and geographical region in insured populations have their counterparts in general mortality experience despite some differences in magnitude of rates. The cohorts assembled for smoking and lung cancer investigations do not appear to have been subjected to more rigorous selection than that encountered by industrial policyholders, nor is there reason to believe that the selection effects which did exist discriminated between smokers and nonsmokers. Even when stronger selection

effects on mortality experience exist, as in the case of ordinary policyholders, it is well known that the selection effects of physical examinations on mortality experience wear off quickly: very conservatively, in 10 years or less (39), usually in about 5 years. If there is any question about the prospective study results on the association of smoking and lung cancer being affected by selection, the conservative course would be to discount the first few years' experience and to require that the early results be confirmed by later experience after selection effects have worn off.

The collation of experience from several studies is also a safeguard against error in generalizing from forward studies on lung cancer. Data from prospective studies may be subclassified by other population characteristics and further checked for internal consistency. With these precautions, the dangers of drawing inferences from forward and retrospective studies inapplicable to the general population seem rather remote.

Summary

The size of the lung cancer problem, as indicated by the number of lives at stake and the economic implications of any potential control measures which might later be advanced, should not blind investigators to the many possibilities for studies similar to those on other chronic diseases which have yielded some of their secrets to the epidemiological approach. Diseases showing pronounced variations in risk among population subgroups are the more amenable to epidemiological study; and lung cancer falls into this category. Studies on human populations should continue to play an important role in delineating possible etiological relationships for lung cancer, the mechanisms for which could then be elaborated by animal experimentation.

Progress must come by the cross-checking of the several results of epidemiological studies, animal experimentation, and other laboratory findings. The issues will probably be settled by an evolutionary process, as was the fluoride-dental caries relationship. Gradually, the meaning of certain associations will become accepted. Dissent will die off and the debate will shift to the many other points in any

epidemiological models still requiring elaboration.

Ninth Annual Seminar on Seafood Sanitation

The ninth annual Seminar on Seafood Sanitation, sponsored by the Virginia and Maryland State Health Departments, was held in Solomons, Md., September 27-29, 1955. More than 50 persons attended the 5 sessions, which included an inspection of an oyster-packing house and a visit by boat to a soft-clam harvesting area on the Patuxent River.

The first Seminar on Seafood Sanitation was held in 1946 because seafood sanitation specialists found that their work required broad up-to-date technical knowledge. In addition to the common food plant sanitation problems, they were concerned with the construction and operation of municipal and private sewage disposal works; they had to make bacteriological, hydrographic, and sanitary surveys of shellfish-growing areas; and they were obliged to apply the results of these studies to decisions on the suitability of an area for shellfish culture. The seminar has provided a forum where bacteriologists, sanitarians, and sanitary engineers working with seafood sanitation in the Chesapeake Bay area can exchange information on such problems of mutual interest.

Many seafood sanitation problems encountered by county, State, and Federal personnel were discussed at the 3-day meeting. These included sanitary surveys of shellfish-growing areas, general food plant sanitation, sanitation of oyster-shucking plants, sanitation problems in the crabmeat industry, sanitary

problems in the new Chesapeake Bay soft-clam industry, preservation of food by radioactive sterilization, and a discussion of the relative merits of State certification of processors of breaded seafood.

Included in the agencies represented in the discussions were State health departments of Maryland, Virginia, South Carolina, Georgia, and the District of Columbia; New York State Department of Conservation; Maryland county health departments which have seafood sanitation programs; the Food and Drug Administration and the Public Health Service; and the Fish and Wildlife Service. The seafood industry was represented by officials of the National Fisheries Institute, the Oyster Institute of North America, and the Oyster Growers and Dealers Association of North America, Inc.

William Ballard, president of the Oyster Growers and Dealers Association of North America, Inc., and operator of one of the world's largest oyster-shucking and packing plants, told of his industry's dependence on sanitation and expressed the opinion that the future of the seafood industry rested with the accomplishments of the fisheries research scientists and with the seafood sanitation specialists.

The participants recommended that the health departments of Maryland and Virginia sponsor another seafood sanitation seminar in 1956.

Federal and State health authorities and representatives of State medical societies met during March and April 1955 to consider the health problems involved in protecting the civilian population from the effects of modern weapons of war. The conferences, which were held in each of the nine regions of the Department of Health, Education, and Welfare, were conducted by the Public Health Service in cooperation with the Association of State and Territorial Health Officers, the Federal Civil Defense Administration, and the American Medical Association. Emphasizing that it expects to discharge its civil defense responsibilities to the very best of its ability, the Public Health

Service reported its existing plans and activities and presented current facts related to defense against biological, chemical, and radiological warfare. An important objective of the conferences was to secure advice from the States as to how the Service can best help them in providing the health services needed in civil defense. One of the conference papers is given here in full, and five others are given in brief. A seventh paper, a discussion of biological warfare defense by Keith H. Lewis of the Robert A. Taft Sanitary Engineering Center, was omitted from this summary. A glossary on radiation terms appears on p. 192.

Biological-Medical Considerations in Atomic Defense

By EDWIN G. WILLIAMS, M.D., and SAMUEL C. INGRAHAM II, M.D., M.P.H.

THIS discussion of defense against atomic attack centers around atomic radiation, as distinct from the blast and heat effects of a nuclear reaction. Right at the start, we need to pause for a moment to gather some perspective on the problem of radiation from a nuclear weapon. As stated in a recent Federal Civil Defense Administration publication (1):

"A surprise daylight attack with a nominal

bomb [20 kilotons] exploded at 2,000 feet over an 'average' metropolitan area would produce a total of about 120,000 casualties—killed and injured.

"Of this total, 40,000 (33⅓ percent) would either be killed outright or would die the first day. . . . Thus, probably 80,000 casualties (66⅔ percent) would survive the first 24 hours. Of these 80,000 it is estimated that:

48,000 (60 percent) would be suffering from burns;
40,000 (50 percent) would be suffering from mechanical injuries;
16,000 (20 percent) would be suffering chiefly from radiation injuries."

NOTE: The total exceeds 100 percent because many of the casualties would be suffering from two or more types of injuries.

Thus, we see that radiation injuries are expected to constitute only a small percentage of

Dr. Williams is a consultant with the Atomic Medicine Health Office, Federal Civil Defense Administration. Dr. Ingraham is head of the General Field Studies Section, National Cancer Institute, Public Health Service. Immediately prior to that assignment, he was assistant chief of the Radiological Health Branch, Public Health Service.

the total injuries caused by an atomic bomb attack. But treatment of burns and traumatic injuries, from which 80 plus percent of the casualties would be suffering, are a well-accepted part of orthodox medical practice; so, albeit somewhat arbitrarily, we are disregarding the vast problems of these injuries. Radiation injuries, on the other hand, are novel to many physicians, and for most nonmedical people they carry an aura of absolute mystery. For this reason alone, we shall limit this discussion almost exclusively to the radiation aspects of nuclear weapons.

The increasing size of atomic explosions and the development of hydrogen-fusion bombs with the power of millions of tons of TNT have recently increased probability of radiation injury from nuclear weapons. The following information, based on an official release of Chairman Louis L. Strauss, Atomic Energy Commission, was published recently (2):

"Fallout from [a] hypothetical H-bomb dropped on Washington, D. C., . . . could cause deaths as far as New York City, 220 miles away. In [a] 10-mile-wide circle everything would be wrecked by blast. Heavy chunks of radioactive debris would rain down. But lighter debris and dust would be blown 80,000 feet high. Assuming . . . that winds are northward [which the prevailing winds are], the dust cloud would drop its radioactive cargo in [a] cigar-shaped zone about 220 miles long and over 20 miles wide. Radiation, decreasing with distance from the blast, would be nearly 100 percent lethal for unprotected persons out to 140 miles from ground zero [these days it really is 'area zero'], diminishing to 50 percent lethal between 140 and 160 miles away, and dropping from 10 percent lethal to safe between 160 and 220 miles away."

Contrast this radiation effect to that of an atomic bomb, where the expected number of persons disabled by radiation is relatively small. The fallout from hydrogen bombs could affect many millions of people. In certain population areas, several million could be exposed to a lethal dose.

Now, with another reminder that radiation comprises only one phase of the medical problem in atomic warfare, we shall consider pertinent biomedical effects of radiation.

How Radiation Affects Tissue

Atomic radiations, whether they arise from nuclear weapons, from radioisotopes or radium, or from radiation-producing machines, share one distinctive property: During the process of absorption in the body, they all interact with tissue by splitting atoms and molecules into pairs of electrically charged fragments called ions (fig. 1).

Figure 1. Ionization of a hydrogen atom by a beta particle.

The remarkable effectiveness of atomic radiations in causing biological injury stems from their property of acting directly on the individual atoms and molecules composing tissue. By their ionizing effect, radiations may eject electrons from atoms, break up chemical compounds, displace atoms in organized molecules, generate toxic substances and, in general, cause important changes in the submicroscopic structure of body cells.

The potency of radiations may perhaps be appreciated more concretely if one compares, for example, the power of alpha particles (to ionize and injure molecules) with the power of shotgun pellets (to injure people). Relative to their respective targets, alpha particles are 28 times heavier than No. 5 shot (fig. 2). And the speed of 1-Mev. alpha particles exceeds the muzzle velocity of No. 5 shot from a 12-gauge shotgun by well over a quarter of a million times. A shotgun fired at a man can injure or kill him. Alpha particles striking tissue can ionize its molecules and injure or kill its cells. A single shotgun pellet, if it strikes a vital spot, can be fatal. A single alpha particle (or for that matter, any other single radiation), if it

ionizes a critical molecule, can kill a cell or possibly start a cancer.

The specific injury produced by radiation in any given circumstance probably depends on many variable factors, such as the density of ionization, the kind of tissue irradiated, and the kind or location of the molecules affected. Observed injuries include the mutation of genes, inactivation of enzymes, inhibition of cell division, and fatal disturbance of tissue functions.

So far as we know, there are four possible re-

mediate external warning that a sublethal or even a minimum lethal dose of radiation has been received. Some changes appear early. Others may be seen only after prolonged periods of latency. Evidence of injury from minimal doses of radiation may not show up for months or even years.

The recognizable changes produced in cells by radiation are of many sorts. They include changes in permeability of the cell membrane, changes in the staining characteristics of cells,

Figure 2. Comparison of the power of alpha particles to injure a molecule with the power of shotgun pellets to injure a man.

sults of exposing a living cell to radiation (fig. 3). The cell may be killed. It may be crippled, transiently or permanently. Or it may merely have nonessential molecules ionized and, therefore, actually not be harmed at all by the radiation. Symptoms of radiation injury (skin erythema, radiation sickness, decreased fertility) appear in an individual only after a sufficient number of cells have been injured or killed. Unless the exposure has been sufficient to cause skin erythema, there may be no im-

changes in viscosity of the protoplasm, changes in chromosomes, swelling of cellular components, production of abnormal cell divisions, distortion of cell structure, and many more obscure but measurable changes.

Variations in Radiosensitivity

Each of the human body's many different tissues responds differently to radiation exposure. The responses, in general, are a summa-

tion of the responses of the various cells and cell types composing the specific tissue.

Rapidly growing or metabolizing tissues are usually more sensitive to radiation than are quiescent tissues. Lymphocytic tissues (lymph nodes, tonsils) are more easily affected than are muscle or nerve tissues. Tissue cells in an organ are more easily injured by radiation than tissue cells grown in a culture.

Figure 3. Diagram of irradiated tissue.

Tissues so differ in reaction to radiation absorption that it is possible to classify them, in a loose fashion, according to the doses of radiation they will successfully withstand. Any such classification is empirical and, since it disregards important variables other than dosage, is far from exact. Various authors place some of the tissues in a slightly different order of radiosensitivity. However, the principle of specific tissue sensitivity is generally accepted. The following list is based on the available data and represents the approximate response of tissues exposed to divided doses of roentgen rays generated at 200 kilovolts (3):

Highly radiosensitive (cells seriously injured or killed by doses of 600 roentgens or less): lymphocytes; bone marrow cells; sexual cells (testicle and ovary).

Moderately radiosensitive (cells seriously injured or killed by doses of 600 to 3,000 roentgens): salivary glands; epithelium of skin; endothelium lining blood vessels; bone (growing); epithelium of stomach and intestine; connective tissue; elastic tissue.

Radioresistant (cells show little damage unless dose exceeds 3,000 roentgens): kidney; liver; thyroid, pancreas, pituitary, adrenal, and parathyroid glands; bone (mature); cartilage; muscle; brain and other nervous tissue.

Quite recently, we have been told that the organ systems most fundamentally affected are

the central nervous system, the blood forming organs, and the gastrointestinal tract. Nerve tissues, for example, do not recover from injury as do many other tissues.

The recovery of tissues showing any specific radiation effect is dependent upon the ability of the individual cells composing it to recover and reproduce. This in turn depends upon the dose of radiation absorbed and the types of cells present. The blood forming organs, the skin, the membranes lining body cavities, and the secreting glands may regenerate completely and resume their normal functions. Muscle, brain, and portions of the kidney and eye cannot regenerate; repair of them results only in scar formation. Even those tissues that can regenerate may fail to respond after repeated ionization and so cause conditions such as nonhealing ulcers or aplastic anemia. Also, repeated regeneration may produce cancerous conditions: epitheliomata, fibrosarcomata, or leukemia. These changes have all been observed in animals following radiation exposures at levels corresponding to doses only slightly above the accepted safe limits for man. There are no constant clinical symptoms which can be relied upon to warn of latent radiation injury before the late changes become manifest.

Not only is there marked variation in radiation sensitivity of different kinds of cells and tissues within an individual; there is also some variation in the radiosensitivity of individuals of the same species and even more variation among different species.

If killing power is selected to measure the effect of radiation exposure and if mice are selected as the test animals, it may be demonstrated that as the dose of X-rays given over the entire body increases from 200 to 1,000 roentgens the acute mortality rate from irradiation in successive groups of exposed mice will increase from 10 to 100 percent. In addition, the onset of lethal effect will show a latent period which shortens from 8 to 2 days or less as the radiation dose is increased.

If the dose of radiation that within 30 days will kill 50 percent of the individuals exposed (median lethal dose or LD₅₀) is selected as a measure of the biological effect of radiation, the variation in radiosensitivity from animal

species to animal species becomes apparent. The approximate LD₅₀ X-ray doses for several of the more common experimental animals (based on actual experiments) and the estimated median lethal dose for man (based on animal experiments, reactions of X-ray therapy patients, and data collected in Japan) are as follows:

<i>Animal</i>	<i>Dose (roentgens)</i>
Guinea pig-----	175-250
Dog-----	325
Goat-----	350
Man-----	400-450
Mouse-----	530
Rabbit-----	800
Rat-----	825-900
Weevils-----	1,000-2,000
Molds-----	2,000
Bacteria (nonspore forming)-----	1,500-2,000
Bacteria (spore forming)-----	20,000-50,000
Viruses-----	50,000-1,000,000

The potency of radiation to injure tissue is possibly better appreciated when one realizes that 1 roentgen produces about 1,000 ionizations among the atoms in each body cell exposed. Since the adult human body is composed of about 140 trillion cells, this means that exposure of the whole body to the maximum permissible dose for radiation workers (0.3 roentgen per week) will result in about 7 quadrillion ionizations per working day in the body. The human LD₅₀ dose (450 roentgens) will ionize about 1 atom in every 100 million in the body, or about 450,000 atoms per cell, on the average.

Effect on Life Expectancy and Fertility

Experimental observations of many different species indicate that radiations induce an aging and debilitating effect. Each roentgen of exposure probably shortens life expectancy of an animal by about one ten-thousandth. This implies that an exposure rate of 0.4 milliroentgen equivalent physical per day (about what man receives from cosmic and other naturally occurring radiation) may shorten the expected life span of a human being by about 4 weeks, if the effect of radiation in man is like that in animals; or 50 roentgens of exposure may shorten the expected human life span by as much as 18 weeks. Also, radiation exposure induces an increased susceptibility to infection.

There is a wide range of specific radiation effects from a wide range of doses. In general, the larger the dose, the more prompt and dramatic are its biological effects; the smaller the dose, the more delayed and more insidious are its biological effects.

In every discussion of the effects of ionizing radiations one of the first questions put to the physician is, "Will it make me sterile?" In response, the physician usually finds it necessary to distinguish between potency and fertility. No direct effects on potency have been reported. Fertility has been affected.

Permanent sterilization of the human female requires 400 to 600 roentgens delivered to the ovary. Sterilization of the human male can be produced by 800 to 1,000 roentgens delivered to the testes. Either of these doses given as whole-body radiation would probably be lethal to the individual, and so danger of causing permanent sterilization by single whole-body exposures becomes a theoretical rather than a practical question. Reduced fertility and temporary sterility have been induced in human beings by single exposures of 200 to 300 roentgens to the gonads and in animals by repeated exposures of as little as 1 roentgen per day for a number of weeks.

A survey a few years ago found that the average number of children born to a group of radiologists was 1.7, whereas the average number of children born to a comparable group of physicians not engaged in roentgenology was 3 (4). Inasmuch as the major difference between the two groups of physicians, so far as could be determined, was the practice of roentgenology, these data may indicate a reduction in human fertility from repeated exposure to relatively small doses of X-rays.

Effect on Genes

Genetic, or hereditary, changes may arise from doses of radiation much smaller than those needed to affect fertility. Many genetic experts believe that *any* amount of ionizing radiations may produce hereditary changes cumulative throughout the lifetime of the germ plasma line that can and will appear in future generations. There is, however, no current evidence that radiation workers (X-ray technicians, radiolo-

gists, atomic workers) who have not abused the maximum permissible dose limits have produced offspring differing from those of the general populace.

Specifically, from the human genetic studies being made of the completed pregnancies among the surviving victims of the atom bombings at Hiroshima and Nagasaki, at least one positive finding has been reported. The expected normal male-female ratio has been upset among offspring of women exposed within 2,000 meters of ground zero (the point immediately beneath the exploding bomb) by a statistically significant decrease in male births (5).

Ionizing radiation can alter the genes in the body (somatic) cells and in the reproductive (sexual) cells and so cause them to grow or reproduce abnormally. If a gene change occurs in a sexual cell, a mutation will occur in later generations provided that the cell is used in reproduction. If a gene change occurs in a cell of growing or regenerating somatic tissue like skin, liver, bone, or bone marrow, it may cause cancerous or other harmful changes in the exposed individual.

Both somatic and sexual cell mutations produced by radiation have been observed in human beings. Statistically significant increases in numbers of mutations have occurred in offspring of parents with a history of exposure to either acute or chronic radiation. An increased incidence of cancers has been recorded in people exposed to amounts of radiation similar to those that produce genetic mutations or cancers in animals. Peller and Pick (6) in 1952 reported that among physicians in the United States, there were 8 to 9 times as many fatal cases of leukemia among radiologist physicians as among nonradiologist physicians.

The probability that a cell may be ionized increases in proportion to the number of cells exposed to radiation. As there are many more somatic cells than sexual cells in the human body, somatic cells are the more likely to be changed genetically from a given whole-body exposure. Thus, from the point of view of radiation-produced gene changes and their effects on human beings, one probably should avoid needless radiation exposure at least as much for his own health protection as for the genetic protection of his progeny.

A Calculated Risk

In the civil defense program, we must think of radiation exposure in terms of calculated risk. Exposures ought to be held as low as possible, but doses permitted must allow for such exposures as are unavoidable in accomplishment of essential missions.

No predetermined dosage schedule can be set, in advance of an emergency situation, that will evaluate the relative importance of a given civil defense mission. This evaluation is a command decision to be made by the responsible civil defense official on the spot, at the time. However, one guide in such decisions will be the following data on radiation effects, which were compiled for the FCDA:

<i>Dose (roentgens)</i>	<i>Observed effects</i>
0-25-----	No obvious injury. An average person receives 10-20 roentgens over a lifetime from naturally radioactive sources.
25-50-----	Least clinically detectable exposure—possible blood changes but no serious injury. 50 roentgens in 1 day is safe if not repeated too soon.
50-100-----	Blood cell changes, some injury, no serious disability. 100 roentgens causes sickness to approximately 10 percent of the persons receiving this dose.
100-200-----	Injury, possible disability, probably no deaths. 150 roentgens causes sickness to approximately 25 percent.
200-400-----	Injury and disability certain, death possible. 200 roentgens causes sickness to approximately 50 percent, death to approximately 2 percent. 300 roentgens causes death to approximately 20 percent.
400-450-----	Fatal to 50 percent of persons exposed; death occurs within 2 to 12 weeks.
600 or more-----	Lethal dose causing death to nearly all persons exposed within 2 weeks.

As with other biomedical values, there is nothing magical about the roentgen values given here. The several effects listed merge gradually one into the other as the dosage increases; so, if another table shows slightly varying values, one should not consider this or that table correct and the other one wrong. Rather, the differences will probably be an expression of the normal range of values seen in any biomedical situation.

Among atomic bomb casualties there will be many with multiple injuries. Dual or triple modes of injury may be the rule rather than the exception. Victims may have burns, traumatic injuries, and radiation injuries in any combination. Prognosis in each case will depend on the types and extent of the injuries. Those with radiation injuries in addition to more orthodox injuries will tend to have a graver prognosis than those not having radiation injuries. The reason for this is that one of the important effects of whole-body exposure to atomic radiation is to impair the effectiveness of body mechanisms responsible for resistance to infection and disease and for healing and repair of injured tissues.

Radiation exposure incurred from the atomic flash is, of course, practically instantaneous. That from radioactive fallout, because of the rapid decay of this material, should be thought of as being suffered within a quite short time span: More than 80 percent of the radiation dose from atomic debris will be delivered within 10 hours of the explosion time. The radiologists tell us that radiation exposures delivered over a time span of minutes or hours may be thought of as having effects identical to an instantaneous exposure of the same roentgen value. On the other hand, exposures incurred over a period of days or months have less total biomedical effect on the body as a whole than would the same cumulative roentgen dose if it were delivered over a period of only hours or minutes.

Radiation Sickness

Radiation sickness is the term used to describe the illness produced by overexposure to atomic radiations. The accumulated evidence indicates that radiation sickness represents a symptom complex which may be divided into the following five groups:

1. *General symptoms*: Headache, vertigo, debility, abnormal sensations of taste or smell.
2. *Gastrointestinal symptoms*: Anorexia, nausea, vomiting, diarrhea.
3. *Cardiovascular symptoms*: Tachycardia, arrhythmia, fall of blood pressure, shortness of breath.
4. *Hematological symptoms*: Leukopenia,

thrombocytopenia, increased sedimentation rate, decreased resistance to infection.

5. *Psychic symptoms*: Increased irritability, insomnia, fear.

Not all the symptoms of radiation sickness occur in each patient. Also, the same patient may react differently at different times to similar radiation doses. In general, the greater the radiation exposure, the quicker and more dramatic is the appearance of radiation sickness. For those interested in more details of human and animal responses to radiation exposure, it is suggested that they refer to the voluminous medical and other scientific literature on this subject.

Therapeutic Measures

There are no known specific agents for the treatment of radiation injury. There are no practical prophylactic drugs to temper or avert radiation injury consequent to adequate exposure to radiation. Medical research is continuing in an effort to discover and develop better means of diagnosis, prophylaxis, and treatment for the victims of all types of radiological hazards, including atomic attack.

The recommended therapeutic measures for radiation sickness and its sequelae are almost exclusively symptomatic or supportive in nature. They include:

1. Bed rest plus sedatives to reduce stress demands on the body economy.
2. Therapy to improve nutrition and maintain fluid and mineral balance.
3. Measures to reduce or prevent infection: Antibiotics; aseptic techniques in nursing and medical care with emphasis on mouth and skin hygiene; leucocytic cream.
4. Antishock drugs.
5. Antihistamines (on the theory that shock is precipitated or made worse by histamine produced by the radiation-injured tissues).
6. Antigastric secretants and antinauseants.
7. Antihemorrhagic drugs.
8. Miscellaneous drugs, such as glucose, glucose-saline injections, cholesterol, liver preparations, numerous vitamins, alcohol, insulin, corpus luteum hormone, Congo red desoxycorticosterone acetate (DCA), and ACTH.
9. Blood transfusions.

The opinions about the therapeutic values of these proposed measures are as varied as the number of substances listed.

Attempts at prophylaxis or prevention of radiation injury by pretreatment has been tried in animals with varying degrees of apparent success. Desoxycorticosterone acetate (DCA) has had some favorable effect in delaying radiation death as have cysteine, glutathione, and rutin. Subcutaneous or intermuscular injection of heterologous bone marrow appeared to have success as a radiation protectant for mice. The latest, most hopeful drug being tried is beta-mercaptoethylamine.

Probably the best summarization of present-day treatment measures for radiation sickness is contained in the final paragraph of the Report on the Medical Studies of the Effect of the Atomic Bomb by Dr. Masao Tsuzuki, professor at Tokyo Imperial University and chairman of the medical section of the Japanese National Research Council. Even though this document is now more than 6 years old, Dr. Tsuzuki's statement is still timely:

"The most important measures for the treatment of the radiation injuries is careful protection. All patients are affected more or less by the radioactivity; these must recover by their own vital power. In the cases in which the vital organs are damaged beyond their ability to recover, medical care at the present time cannot help. We may have some hope of recovery as long as any reserve power is remaining because the radiation exposure has occurred only once. We must, therefore, avoid such treatment as whipping a tired horse hastily. In other words, we should not be overconfident in the ability of our medical care. Our aim shall always be a promotion of the natural healing powers."

Public Reaction

Quite as serious as the physical problem of radiation control is the problem of the public's psychological reaction to the use of radiation.

Misunderstanding of radiation coupled with fear of the unknown are usually enough to make a public wary of anything connected with atomic radiations. An injudicious warning about radiation may needlessly increase the difficulty of civil defense activities in the presence of atomic attack. On the other hand, it may be an even worse mistake to pay no heed to the hazards. Public health and civil defense workers can meet this issue by viewing radiation in proper perspective so as to establish and maintain measures for protection without doing psychological damage by their attitudes and statements. Once exposure has occurred, little can be done about the injury. It will not improve the situation to alarm or depress those who have been injured.

Radiation constitutes only a portion of the problems created by nuclear weapons. The major companion problems will be care for burns and traumatic injuries plus an enormous task of sanitation and hygiene for the homeless and dispossessed.

Radiological Defense

Radiological defense is a part of the integrated defense system of this country. It requires the knowledges and skills of specially trained technicians. However, many simple precautions of a nontechnical nature can be utilized to protect the public.

The detonation of a nuclear weapon is accompanied by the physical phenomena of light, heat, and blast and also by instantaneous nuclear radiations. The magnitude of each of these phenomena is proportional to the energy released in the detonation. Since we cannot see, hear, feel, taste, or smell ionizing radiation and radioactivity, they must be detected and their magnitude measured by sensitive instruments.

A great deal of what has been written about the effects of nuclear weapons is summarized in the accompanying chart. Incident thermal radiation on exposed skin will cause a first degree burn if the intensity is 2-3 calories per square centimeter, a second degree burn if the intensity is 3-7 calories per square centimeter, and a third degree burn if the intensity is 8-10 calories per square centimeter. An overpressure of more than 35 p.s.i. is required to do bodily harm to a person by blast alone. An overpressure of 19 p.s.i. will damage buildings irreparably; 19-6.6 p.s.i. will cause heavy damage; and 6.6-3 p.s.i. will cause moderate damage. Nuclear radiations released at the time of the explosion do not present a serious hazard beyond the effective range of heat and light. A longer-term hazard is created by the byproducts of the reaction: radioisotopes which fall out of the clouds.

Fallout and Monitoring

As the cloud raised by a nuclear blast carries radioactive dust and debris aloft, this matter is swept out by shearing winds. The constituents

By Simon Kinsman, Ph.D., associate chief of the Training Section, Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio.

of the cloud from a large thermonuclear weapon are as radioactive as millions of tons of radium. Fallout contains many species, or kinds, of radioactive materials, each of which decays at its own specific rate. Decay means that the atoms change to other elements; in the process radiations are released. The apparent radiation released by the fallout during the decay process is actually the sum of the radiations released by each individual radioisotope present. Both the decay rate and the intensity of radiation released in the decay process are indicated by the half-life of the material. The half-life is the time required for one-half of the atoms of a given material to decay. The shorter the half-life, the faster the decay and the greater the intensity of radiation produced by the decay process.

To monitor, or measure, the extent and magnitude of radioactive fallout, trained personnel use radiation detection instruments. Monitoring by plane is recommended in the early stages; ground monitoring should follow. The area contaminated by a fallout may be larger than 10,000 square miles.

Estimating the Hazard

The half-lives of the radioactive materials in the atomic cloud range from a few seconds and minutes to thousands of years. The fallout will contain many radioactive species, some of which can be an internal hazard if admitted to the body, and all of which can constitute an external hazard when outside but in the vicinity of the body.

Estimates of the amount of radiation which a person might receive while in a fallout area are based on an empirical relationship between the initial intensity of the radiation from all the fallout materials, the time elapsed between the detonation and the start of exposure, and the length of time in the area.

As soon as the aerial monitoring crew can furnish a reading of average radiation intensity for an area or as soon as the ground monitor can give an average radiation intensity for a street, block, or even a room which has been contaminated with fallout, it is possible to calculate the intensity of radiation in that locality at any future time, providing, of course, that no decon-

tamination procedures are used and no additional contamination occurs. Tables, curves, and slide rules are available from which solutions to the problem can be read directly.

If the intensity of radiation remains relatively stable, as it does in the vicinity of long half-life radioactive materials, such as radium, uranium, or plutonium, the total dose of radiation can be determined simply by measuring the radiation intensity with an appropriate instrument and multiplying the result by the exposure time. When the intensity is on a sharply declining scale, as it is in a fallout area, probable exposure can be estimated by means of calculus. Tables, curves, and slide rules are also available for obtaining solutions to this problem directly.

Decontamination

Radiological decontamination is still an unrefined science. Wise counsel is to avoid contamination if possible.

There is no practical way to destroy radioactivity. Since radioactive decay is entirely unaffected by physical or chemical reactions, decontaminating solutions such as those used in neutralizing mustard gas contamination are of little value against radioactive materials. The objective of radiological decontamination is to free an area from persistent radioactive agents. This necessitates removal and segregation of microscopic quantities of induced radioactive isotopes, fission products, and unfissioned parts of the bomb fuel.

Currently accepted principles of decontamination suggest the following procedures:

1. Immediate reduction to a minimum of that contamination of personnel and vital installations which cannot be or has not been avoided, by means of (a) complete bathing, monitoring, reclothing, administering of medical treatment when required, and evacuation of affected personnel; (b) washing and scrubbing down exposed surfaces to free them of loose contaminating particles; (c) temporarily covering short-range emitters (alpha or beta) with a coating, such as paint, to provide a partial shield against the emissions and prevent the spread of contaminants.

2. Subsequent thorough decontamination of

Distances from explosion at which various effects are produced as function of bomb energy.

areas important enough and of low enough radiation intensity to warrant such action, which may include (a) repeated scrubdowns; (b) removal and collection of closely adhering particles by using such chemicals as citric or hydrochloric acid, which make the particles more soluble; (c) removal and segregation of the surface to which the particles cling by using paint-removing solutions, scraping, or possibly wet sandblasting (if the surface material can be gathered for segregation).

3. Prevention of the spread of contamination, which may be accomplished by (a) preventing access to particularly "hot" areas; (b) using great care in disposing of grossly contaminated objects and the water and materials used in removing contaminating particles; (c) carrying out a carefully prescribed ventilation doctrine in air-conditioned shelters; (d) improvising a change station or decontamination center for the thorough decontamination of personnel and

their clothing and equipment (clothing may have to be buried).

The value of the operations mentioned in "1" and "2" should always be weighed against the possibility of temporary or permanent abandonment of the area or installation or the possibility of prescribing maximum periods of working time therein.

Salvaging Food and Water

Food in the damaged area may contain some induced radioactivity, but it is unlikely to be present in hazardous amounts. The largest source of contamination is fallout. Radioactive dusts may be deposited on foods or in water.

With respect to food or water that may be seriously contaminated, remember that radiation is less of a hazard when the source is outside the body than when it is within the body. Decontamination or shielding of the skin is far easier than decontamination of the lungs, liver, or bones.

To prevent accidental ingestion of radioactive materials, isolate all unpackaged foods that were located where the dust from a ground burst or mist from an underwater burst might have settled on them. Before opening canned or bottled foods, wash the outside of the container thoroughly. Also scrub all cooking utensils and tableware exposed to radioactive dust or mist. Foods and utensils in tightly closed drawers or cupboards will not be contaminated by fallout.

Water inside household pipes at the time of the explosion will probably not be seriously contaminated. If pressure is available, a little water can be drawn off immediately after the burst and placed in clean containers with covers. This water will be safe for consumption. Although the chances that the city water supply will be radioactive are pretty slim, be cautious about using tapwater for drinking thereafter. If possible, wait until official word is received that the water is safe.

General Information

All radiation is damaging and should be avoided whenever possible. In time of disaster, standards of permissible radiation tolerances

will have to be changed from peacetime to emergency levels. The amount of exposure to radiation will have to be weighed against the necessities; that is, it will be a calculated risk. If protective practices are observed, however, the chances of survival will be increased.

Alpha, beta, and gamma radiation will not cause foods, water, or the person to become radioactive. Neutron flux may induce some radioactivity, but everything within the neutron range will probably be damaged beyond recovery by blast and heat. Radioactivity in foods, water, or the body is the consequence of deposits of radioactive elements produced by nuclear reaction.

Because radioactivity cannot be liquidated, the handling of people or objects contaminated with radioactive materials is somewhat different from the handling of people or objects contaminated with any other type of dust. If a person handles people or objects contaminated with radioactive materials, he himself will not become radioactive, but some of the radioactive dust may attach itself to his clothing or body. Decontamination usually takes the form of scrubbing with soap and water. However, since you can't destroy radioactive materials, the wash water must be so disposed of as to guard against entry of the materials into the water supply.

In regard to shelter and shielding from radiation resulting from radioactivity in the fallout area, as long as we can prevent internal contamination, we need consider only gamma radiation. Assuming that the shelter is beyond the range of the instantaneous gamma radiation produced by a 15-megaton weapon, the following tabulations, prepared by Dr. R. E. Lapp, show the extent of the fallout areas that may be expected from this weapon, the average intensities of radiation in these areas, and the corresponding attenuation of radiation that may be expected from shielding material:

<i>Time after burst (hours)</i>	<i>Fallout area (square miles)</i>	<i>Average intensity of gamma radiation (roentgens/hour)</i>
1	250	2,500
3	1,200	200
6	4,000	30

<i>Reduction factor</i>	<i>Concrete (inches)</i>	<i>Packed soil(inches)</i>
10	6	11
50	11	18
100	13	21
1,000	19	30

It has been reported that a dose of whole-body radiation of 600-700 roentgens received in a short period of time would be fatal to all recipients. An unprotected person in the 250-square-mile area 1 hour after the atomic explosion would receive this radiation dose (625 roentgens) in 15 minutes. However, if a person were behind 30 inches of packed soil or 19 inches of concrete, the radiation intensity would be reduced by a factor of 1,000 and he would receive radiation only at the rate of 2,500/1,000, or 2.5, roentgens per hour. This dose rate would diminish with time, and the chances are that the person behind this shield would not suffer serious effects from the exposure.

Chemical Weapons

PHR The threat of the employment of poison gas as a weapon of war presents a problem which cannot safely be ignored by either military or civil defense planners. This fact is well recognized by the military staffs of all major powers, and it has always been an important consideration in the civil defense programs of the European countries.

Prior to World War II, it could perhaps be accepted that the logistical requirements of long-range air attack with the then known toxic agents provided a margin of safety for the United States. Except for the doubtful event of an enemy securing a beachhead on our shores or in some nearby territory, it seemed unlikely that the citizens of this country would be exposed to the cyanides, the mustards, or the phosgenes.

Developments during and since the war have completely changed the situation. The emergence of the nerve gases, sometimes called G agents, as toxic agents produces a threat to people located anywhere that a plane or guided missile can reach. These agents are in the pos-

session of both democratic and Communist forces. And the extreme lethality of these new organo-phosphorus compounds meets all the logistic requirements for long-range attack. Nerve gas is a killing and disabling instrument—make no mistake about that—and it produces these effects with relatively minute quantities compared to the older compounds.

Effects of Nerve Gases

Nerve gases, either in the liquid state as loaded in munitions or in the vapor state following shell or bomb detonation, are colorless and virtually odorless. In the vapor form they may attack through the eyes, or they can be inhaled or ingested. In the liquid form they can be ingested, or they may attack systemically through the unbroken skin. The symptomatic effects usually follow this sequence: contraction of the eye pupil, tightness of the chest, labored breathing, nausea and diarrhea, muscular twitching and convulsions, and rapid death unless counter-measures are taken promptly. Death occurs in a matter of minutes for unprotected individuals exposed to lethal concentrations of nerve gas.

These substances are the most powerful enzyme inhibitors known. A nerve impulse reaching a muscle plate produces acetylcholine from the choline and acetate in the tissue. This acetylcholine, which stimulates the parasympathetic nerve system, is normally controlled by cholinesterase. Nerve gases and cholinesterase react irreversibly in the tissue fluid, permitting the acetylcholine level to build up and causing continual stimulation of the parasympathetic nerve system.

Rapid use of blocking agents, such as atropine salts, is required to nullify the effect of the acetylcholine. The atropine salts, usually in the form of the sulfate or the tartrate, are made in ampins or syrettes containing 2 mg. each. Atropine self-injection devices for treatment of nerve gas casualties are being stockpiled by the Federal Civil Defense Administration.

Following exposure to a nerve gas attack, it is recommended that, if pupillary contraction or difficulty in breathing is encountered, an injection of atropine be administered at once. If the symptoms progress rapidly to the convulsive stage, two more injections of 2 mg. each should

By Harry P. Kramer, M.S., chief of the Training Section, Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio.

be given immediately. An unconscious person should receive three injections, totaling 6 mg. of atropine, followed by artificial respiration.

Because of difficulties associated with self-treatment, it may be advisable to recommend to the public that atropine injections be given by someone else whenever possible. However, in the event of a successful gas attack, affected persons within the zone of the gas cloud, including those in the impact area and downwind, must be treated promptly to prevent death.

Detection and Identification

Special kits have been developed by the Chemical Corps of the Army for detecting and identifying chemical agents encountered in the field and for collecting samples for laboratory identification.

If used overtly, chemical agents probably would be disseminated in the form of a cloud set up by aerial attack. We would expect the nature and extent of this cloud to be defined by trained civil defense workers using equipment identical or similar to that employed by the military for detection and identification. Areas contaminated with liquid nerve gas must be clearly marked with warning signs or tapes, since toxic vapor will rise for some time after the actual missile explodes.

Chemical agents might also be used covertly—to contaminate our water or food supplies, for example. Kits have been developed for detection of contaminants in these media, and it is planned to train civil defense public health workers how to use such devices and how to interpret the results.

Defensive Measures

The havoc a gas attack is capable of producing must receive serious consideration in our civil defense planning. Certainly to ignore these weapons would increase our vulnerability. The use of nerve gases against an ill-informed and unprotected public would create hysteria and panic almost beyond the imagination. Without gas masks or gas-proof shelters, the casualty rate would be enormous.

A gas mask is the only sure protection against nerve gas or any of the other toxic agents that

might be used. At the request of the Federal Civil Defense Administration, the Army Chemical Corps is developing an effective gas mask for use by civilians. The result of several years of research, this mask has several new features. No cannister is used, for example. Instead, there is a so-called diffusion board. One breathes through the sides of the mask rather than through a device attached to the sides or bottom. The mask will have to be made in various sizes to accommodate individual faces. The estimated cost is slightly more than \$2.

Already available is another type of gas mask, which is the approved model for civil defense workers. It is a heavy duty type, very similar to the military mask, for use by rescue and monitoring personnel.

A device to protect preschool-age children and babies, who cannot be fitted with a gas mask, is being developed.

Poor shelter from a gas attack is afforded by ordinary enclosed spaces, such as rooms or buildings. In fact, the danger may increase in such spaces after the cloud passes, since residual concentrations may be trapped within the enclosure. Both exposure time and concentration of the substance are important factors, particularly for agents, such as the nerve gases, which the body cannot detoxify. The same effect may be produced by halving the concentration and doubling the exposure time, for example.

Sealing off openings and cracks in a shelter will help prevent penetration of the vapors. Group shelters from which contaminated air is excluded by filtering devices are feasible.

In summary, modern chemical weapons are extremely toxic and can be delivered upon critical targets in our country. Their physiological action produces characteristic symptoms at such a rapid rate that recognition of the early symptoms serves as an effective means of detection. Protective equipment can be produced. But, until and unless this equipment is available—and it is not today—the United States presents a most attractive target for mass casualty attack with nerve gas. Postattack therapy is possible but of little value without protection for both casualties and first aid personnel.

Biological Hazards

PHR

Civil defense responsibilities in connection with communicable disease control are so closely related to peacetime activities that major differences exist primarily in emphasis. We have made much progress in the continuing battle against communicable diseases. In a disaster, however, conventional protective measures are likely to be impaired. There is also the possibility of deliberate introduction of disease agents, which may be considered as an adaptation, or perversion, of naturally occurring biological attacks.

Thus, the Public Health Service Communicable Disease Center is able to accept its responsibilities in civil defense by extending and increasing its normal operations. This discussion will be directed primarily toward the investigative activities needed to prepare for wartime health emergencies.

Natural Disease Outbreaks

In this country, many of the communicable diseases are held in check by the combined effects of a relatively high standard of living and widely employed public health practices of immunization, water treatment, milk pasteurization, environmental sanitation, and good nutrition. The destruction of shelter, water supply installations, and sanitary facilities, the movement or concentration of large population groups, and the lowering of individual resistance by exposure, inadequate or improper diet, and lack of immunization, all of which may be associated with modern war, could reduce our defenses against disease to a primitive state. Such reduction in our defenses could well be followed by an increase in communicable diseases to epidemic proportions. Hence, we must prepare to maintain as far as possible our present methods of control during wartime,

By Theodore J. Bauer, M.D., chief of the Public Health Service Communicable Disease Center, Atlanta, Ga.

and we must carry on a continuing search for new and more effective procedures.

The center's current program includes developmental studies in the form of laboratory and field research intended to provide new or better methods for control of diseases. As these methods are field tested, they are demonstrated in State and local areas. Training or assistance with training is provided for professional health personnel. Also, equipment and personnel are supplied to communities in the event of epidemics or disasters which cannot be handled by local resources.

Such activities are in the direct interest of our survival during wartime. The needs of civil defense demand that communicable disease research also look at the exotic diseases and the old diseases which may well be revived under emergency conditions. Thus, civil defense requires a communicable disease program broadened to include all likely occurrences and intensified so that each unit of the public health system can operate effectively during emergencies.

One of the problems that may arise in wartime is the exposure of the surviving human population to disease transmitted by rodents and by insects, such as blowflies, which are not ordinarily associated with disease transmission. The development of a chemical treatment for carcasses to prevent both fly breeding and rodent feeding would be the ideal means of solving this problem. Preliminary studies in the Savannah laboratories of CDC have established the potentiality of protecting bodies from blowfly breeding by use of certain pesticides. Plans are being developed for testing additional pesticides and for improving methods and equipment used in the application of these substances against both flies and rodents.

Biological Warfare

Certain diseases which may be of relatively little importance in peacetime could assume great significance in biological warfare. Since the majority of biological warfare victims would be those whom the agent reaches directly, it is imperative to know quickly when, where, and what agent was used. Among the most pressing needs in biological warfare defense,

therefore, are rapid and effective means of detecting, recovering, and identifying pathogenic organisms in air, water, and foodstuffs—and possibly in the soil.

Because a likely form of biological attack would be through the formation of aerosol clouds containing pathogenic agents, a prime essential of biological warfare defense is the development of methods and equipment to collect these organisms from the air. Ideally, sampling devices should operate on a 24-hour basis. To reduce to a practical minimum the manpower necessary to operate the devices in this fashion, semiautomatic equipment must be developed.

An obvious corollary to improvement in sampling is the need for methods of rapidly identifying organisms which are considered potential biological warfare agents. Serologic methods have shown the greatest promise to date. Ordinary serologic procedures have the disadvantage of requiring fairly large numbers of organisms and hence a period of time for cultivation of the organisms. A current CDC project concerns methods of identifying pathogenic organisms when only small numbers are present. Promising results have been obtained in preliminary studies with fluorescein-tagged antibodies. In this technique, high-titered antisera, specific for pathogenic organisms which are considered potential biological warfare agents, are developed in laboratory animals. The antisera are then associated by chemical means with a fluorescent compound. When homologous organisms and fluorescein-tagged antibodies are combined, the organisms will fluoresce under ultraviolet light.

Chemical Warfare

Although communicable disease control would not appear to be directly related to defense against chemical warfare, actually certain principles and activities are parallel. Since 1949, the Communicable Disease Center has been making extensive studies of insecticides, including the organic phosphorus compounds which are chemically related to and produce essentially the same physiological effects as the nerve gases. These studies have included field and laboratory investigations concerned with

toxicity of the compounds under varying conditions, detection and prevention of hazards involved in their use, and treatment of workers exposed to them. Much of the information gained is applicable in civil defense against chemical warfare agents.

Supplementary investigations specifically designed to meet civil defense requirements are needed, however. Problems that should be studied include: development of automatic devices and techniques for rapid detection of nerve gases and feasibility of including such equipment as an integral part of the automatic public warning system; inactivation of nerve gas aerosols by means of counteraerosols or smokes containing mild alkali; effectiveness of protective devices and clothing against nerve gases; persistence of toxic substances on foods and surfaces; decontamination techniques for buildings, clothing, and environment; rapid screening for cholinesterase determinations; and treatment of poisoned persons.

Sanitary Engineering

Civil defense research activities of the Robert A. Taft Sanitary Engineering Center are of the type for which its facilities and staff are well suited. Progress in the projects assigned late in 1954 is summarized here.

Water Supply Protection

Research concerning protection of water supplies has two primary aims: (a) to develop feasible methods of reducing the hazards to water supplies from overt or covert attacks with biological, radiological, and chemical agents and (b) to develop methods for supplying safe potable water during emergencies.

The plan for accomplishing the first of these aims calls for:

By Harry G. Hanson, M.S.S.E., director of the Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio.

1. Evaluation of the hazards to water supply sources of enemy attack with the various special agents.

2. Additional laboratory investigations of the ability of water treatment processes to remove or inactivate various agents.

3. Development of new or improved methods of removing or inactivating these agents.

4. Field trials of the methods developed.

The plan for accomplishing the second aim includes:

1. Determination of needs for emergency water treatment facilities, particularly in areas to which people will be evacuated from target cities.

2. Development of the simplest and least expensive, but reliable, emergency treatment methods.

Several projects already under way are providing valuable information concerning protection of water supplies. One, which is under the sponsorship of the Bureau of Yards and Docks of the Navy, is aimed at developing design criteria and operating instructions for protection of naval continental shore base water supplies from biological, chemical, and radiological agents. We are also studying the ability of existing municipal water treatment methods to remove various concentrations of coliform organisms from raw water; the fate of fallout in the environment after atomic bomb tests; and disinfection materials and techniques. Tentative findings concerning the hazards to water supplies of the various special agents follow.

Biological Agents

A number of biological agents will effectively contaminate water, and the use of these agents by saboteurs is a distinct possibility. Every house connection, every fire hydrant is a possible point of entry by a contaminant. Policing of a large municipal water distribution system to prevent such contamination is out of the question.

The exact quantity of material required to produce an infectious dose of the various biological agents is not known, but it is estimated from limited information on oral infectious doses that 1 to 10 pounds of material would be sufficient to contaminate a million gallons of

water. Each cupful of this million gallons would contain an infectious dose.

We see no way of protecting municipal water systems against a determined saboteur. However, we believe that entire cities would not be attacked. It seems more probable that bacterial sabotage would be directed against critical industrial, military, or other particularly vital elements of a city. Re-treatment of water, provision of an auxiliary supply, or storage near the point of use are the only sure means of protecting against such sabotage. Our studies are aimed at determining how much treatment may be needed, whether disinfection alone will suffice, or whether more complete treatment must be provided.

Detection of biological agents in water is likely to be too slow to prevent infection. As yet, too little is known about the normal variation in chlorine residual in municipal distribution systems to warrant use of chlorine residual measurements for monitoring water for presence of contaminants. Visual detection of bacterial contamination is not feasible because of the high concentrations of organisms that would be required.

Knowledge of the ability of water treatment processes to deal with biological contaminants is extremely limited. We know that chlorine in concentrations of less than 1 p.p.m. will deal effectively with contamination by vegetative bacteria if the chlorine is not in a combined form. We know the chlorine requirements for killing the cysts of certain protozoan parasites. But little is known about the ability of water treatment processes to remove viruses or rickettsiae, or the chlorine doses necessary to kill certain spore-forming bacteria, or methods for removing or detoxifying organic toxins.

Chemical Agents

The standard chemical warfare agents are relatively unattractive as intentional water contaminants. The nerve gases, for example, although among the most toxic chemicals known, are considered less of a danger than some of the biological agents. Their toxic effects are exhibited so promptly and so dramatically that their presence would be suspected as soon as a few people had used the water.

Methods for removing nerve gases from wa-

ter have been developed by the Chemical Corps of the Army and tested by the Corps and the Army's Engineer Research and Development Laboratory. These gases hydrolyze readily at high pH values. Hence, in the event of incidental contamination of water supplies as a result of missiles containing chemical agents falling into the water system, adjustment of the pH to about 10 will lead to the hydrolysis of nerve gases to relatively nontoxic products within a comparatively short time. A method for detecting nerve gases has also been developed by the Chemical Corps, and kits for use in detecting these and other chemical agents in water are available.

The possibility exists, of course, that chemical agents unknown to us are available to an enemy. If other materials do become known, it may be necessary to revise our estimate of the hazard of chemical agents to water supplies.

Development of a monitoring device that will detect any chemical agent and perhaps some toxins may be possible. We are now studying the use of fish, which are much more sensitive than humans to toxic chemicals, as detectors.

** Radiological Agents*

Although radioactive materials are not considered probable intentional contaminants, there are hazards to water supplies from the radioactive fallout produced by an atomic explosion. Thermonuclear weapons may be detonated at levels which give rise to considerable fallout. However, to what extent these weapons will affect water supplies, we are not ready to say. It is certain that the hazards associated with the use of water contaminated by man-made radioactive elements will not decrease as rapidly as the radioactivity in the water decreases, because the most dangerous of the radioisotopes from the standpoint of internal use have relatively long half-lives. Some water sources may remain dangerously contaminated long after external exposure to radiation from fallout on the ground has declined to tolerable levels.

Additional information on the physical and chemical characteristics of the fallout material is needed to help evaluate the hazards to water supplies. The Public Health Service and

others have shown that standard water treatment processes are of limited use in removing soluble radioactive materials. The hazardous isotopes, particularly those of strontium, barium, and iodine, do not respond well to standard water treatment processes. If water supplies are heavily contaminated with these materials, and if the elements are not so closely associated with particulate matter as to be removed with the particles, expensive treatment, such as ion exchange or distillation, will be required to restore safety to drinking water.

Food Protection and Decontamination

One of the first problems following an attack with biological, chemical, or nuclear weapons will be to provide safe food to the surviving population. The Public Health Service shares the responsibility for planning to meet this problem with the Department of Agriculture and the Food and Drug Administration. The Public Health Service area of planning includes the protection and sanitation of milk supplies and other foods in retail markets, restaurants, other public places, and in the home.

Research needs fall into four principal categories: (a) rapid procedures to distinguish the nature of the contaminant; (b) means for preventing or eliminating contamination by biological and chemical aerosols and radioactive fallout; (c) practical decontamination procedures for foods; and (d) problems of sanitation and emergency storage of foods needed for mass feeding of displaced persons.

Emergency decontamination of other essential items (food containers or packages, eating and drinking utensils, clothing, and bedding) and of the person and the shelter area is also being studied. Under some conditions and for some items, routine cleansing with soapy water may be the most important phase of decontamination. Information will be obtained on the probable kinds, amount, and persistence of contaminants, as well as the effectiveness of available decontaminants under emergency conditions.

Rapid Identification Methods

We are seeking to adapt membrane filter procedures and infrared spectrophotometry for use

in the rapid isolation and identification of bacteriological agents from mixed bacterial populations.

When dried smears of bacterial cells are subjected to infrared spectrophotometry (wave length 5μ to 12μ), characteristic and identifying spectra are obtained. The characteristic absorptions are reproducible within plus or minus 2 percent, provided the bacterial cells are grown under carefully controlled conditions and provided the infrared spectrophotometer is carefully set, balanced, and operated. The spectrographic data can be transferred to punch cards and identification readily established by matching unknowns with knowns. The procedure can be accomplished within a few hours after sufficient bacterial cells are available. At the present time, about 1 mg. of cells is required, but recent developments indicate that satisfactory spectra may be obtained on as little as 0.1 or possibly 0.01 mg. of cells.

Bacterial cells grow on the membrane filter in 10 to 20 hours. The time required depends on the specific organism and other factors. Because the filter is an efficient means of concentrating the organisms from dilute suspensions in fluid or gaseous menstrua and because the organisms grow in situ, membrane filter procedures offer time advantages over conventional fluid or agar media in the production of pure colony growths from mixed populations. By transfer of single colony growths to standard medium, followed by 6- to 8-hour incubations, sufficient pure culture cells for infrared spectrophotometry become available.

We believe that, by using a relatively few (4 to 6) basic differential media, the potential bacterial pathogens can be grown on the membrane filter and tentatively differentiated from non-pathogenic species. Incubation of suspicious colonies on a standard medium for a few hours will supply sufficient cells to allow completion of identification by infrared spectrophotometry. We believe this procedure is capable of detecting and identifying pathogens present in relatively small numbers, even when they are mixed with relatively large numbers of nonpathogenic organisms. The entire process of detection, isolation, and identification could take less than 30 hours.

The available information regarding the detection and identification of chemical agents is being reviewed, with emphasis on the nerve, cyanogenous, mustard, and arsenical gases.

PHS Responsibilities

Prompted by the reasoning that public health phases of civil defense should be "built in" with existing public health programs, the Federal Civil Defense Administration delegated public health civil defense responsibilities to the Department of Health, Education, and Welfare on July 14, 1954. It was felt that the Public Health Service could carry out these responsibilities efficiently and economically through well-established channels. It was recognized, further, that civil defense will be a long-range activity and that it therefore requires continuing program attention.

The following functions have been assigned to the Public Health Service:

1. Plan a national program, develop technical guidance for the States, and direct Federal civil defense activities concerned with research relating to the detection, identification, and control of: (a) communicable diseases in man, (b) biological warfare against man, (c) chemical warfare against man, and (d) other public health hazards.
2. Plan, develop, and direct Federal activities concerned with a national program designed to provide Public Health Service reserve personnel from support areas to areas damaged by enemy attack.
3. Plan, develop, and distribute, through appropriate channels, technical guidance concerning the provision of shelter and other protective measures designed to minimize injury to personnel and to reduce damage to vital functional components of public health facilities.
4. Plan a national program, develop technical guidance for States, and direct Federal

By Leroy E. Burney, M.D., an Assistant Surgeon General of the Public Health Service and deputy chief of the Bureau of State Services.

activities concerned with emergency restoration of community facilities essential to health or functional components thereof for which the Public Health Service normally has operating programs.

Planning Assumptions

The Public Health Service civil defense work program for fiscal year 1955 was based on the FCDA planning assumptions for that year. The highlights of these assumptions are:

1. An enemy has the capability of striking any target in the United States.
2. Such attack, if it comes, will consist principally of nuclear (including thermonuclear) weapons delivered by air. These weapons might be delivered by submarines, or they might be smuggled in.
3. Additional weapons, requiring special measures to meet large-scale attacks, will be biological and chemical agents.
4. High-explosive and incendiary bombs are also possible weapons.
5. Preparation must be made to meet psychological warfare and sabotage. Sabotage may include attempts to disrupt industries and communications and covert attacks with biological and chemical agents.
6. The initial attack will be in the nature of an attempted knockout blow, but recurring attacks may be expected.
7. The size of the bombs will range from a few thousand tons to millions of tons of TNT equivalent. One bomb will be sufficient to destroy the largest city.
8. Approximately 1 hour's warning will be received in most areas—possibly less time in some coastal areas and more time in inland areas.
9. Mass evacuation of target cities will provide the best means of reducing casualties.
10. Any area attacked will require outside support; mutual aid will be helpful but it will not be sufficient alone. Both mobile and fixed support from the State attacked, other States, and Federal sources will be required.

We understand that many of the 1955 assumptions, such as the probability that biological and chemical weapons, as well as nuclear weapons, will be used against us, will be carried over

to the planning assumptions for fiscal year 1956. However, a major change is expected as a result of the recent Atomic Energy Commission release concerning radioactive fallout from explosion of a thermonuclear bomb. The release emphasized that it is not possible to apply a single fallout pattern to all thermonuclear detonations. This is true even under test conditions, when the bomb size is known, since the nature of the ground where the explosion occurs, the size of the resulting particles, and the variable directions and velocities of the winds at different levels all have to be considered. With adequate knowledge of atmospheric conditions, however, the fallout pattern usually can be predicted with considerable accuracy.

In the Bikini test of March 1954, the area of extreme hazard from fallout was up to 20 miles wide and 140 miles long downwind from the explosion and about 20 miles upwind and crosswind. The area of some hazard extended approximately 100 miles farther downwind and 20 miles farther to the sides.

Outline of the PHS Program

The Office of the Surgeon General has the overall responsibility for civil defense planning and program development in the Public Health Service. In addition, this office is conducting a project concerning the adaptability of military chemical warfare defenses to civil defense needs.

The National Institutes of Health are conducting investigations designed to lead to improvement of vaccines and other immunizing procedures. Some of their research is directed toward the development of better adjuvants and the determination of effects of known adjuvants with different vaccines. They are also studying preparation and evaluation of purified antigens in experimental animals and the effects of combined antigens in reduced amounts. The goal for this year is to determine whether or not combinations of certain antigens will produce adequate immunization in experimental animals and the minimum amounts that will produce satisfactory immunity. (Since the date of the civil defense conferences, this work has been suspended temporarily.)

The Bureau of State Services will keep the

States informed of the results and means of application of all research relating to biological and chemical warfare hazards and other public health problems. Upon request from the States, the Bureau will provide training courses for key health personnel and for trainers, who, in turn,

can train others. To the limit of its resources, the Bureau will provide assistance in planning State studies and operations. The Public Health Service regional offices will be the channel between the Public Health Service and the States.

Glossary of Radiation Terms

Alpha particle: Charged particle, having a mass of 4 units and 2 unit positive charges of electricity, which is emitted from the nucleus of some atoms. It is composed of 2 neutrons and 2 protons.

Alpha ray: Stream of fast-moving alpha particles. It is a strongly ionizing and weakly penetrating radiation.

Atom: The chemical unit of which all matter is made. It is the smallest particle of an element capable of entering into a chemical reaction.

Atomic radiation: Radiation produced by energy changes in atomic nuclei or atomic electron clouds; ionizing radiation.

Background radiation: Ionizing radiation produced by cosmic radiation and naturally occurring trace amounts of radioactive elements.

Beta particle: Charged particle, having a mass and charge equal in magnitude to those of the electron, which is emitted from the nucleus of some atoms.

Curie: Standard measure of the rate of radioactive decay; the quantity of any radioactive substance in which the number of disintegrations per second is 3.7×10^{10} . The radioactivity of 1 curie of a substance is comparable to the radioactivity of 1 gram of radium.

Decay: Disintegration of the atomic nucleus of an unstable element by the spontaneous emission of charged particles or protons or both.

Electron: Negatively charged particle which is a constituent of every atom; unit of negative electricity equal to 4.80×10^{-10} electrostatic units. Its mass is about $\frac{1}{2000}$ of that of a proton.

Electron volt: Amount of energy gained by an electron in passing across a potential difference of 1 volt.

Equivalent roentgen: Amount of radiation which produces in air an amount of ionization equal to that produced by 1 roentgen of X-radiation or gamma radiation.

External radiation: Radiation entering the body from without.

Fallout (radioactive or atomic): The radioactive dust and atomic or hydrogen bomb debris that falls to the ground downwind from an atomic explosion.

Film badge: Small piece of X-ray or similar photographic film enclosed in a lightproof paper, usually crossed by lead or cadmium strips, carried in a small metal or plastic frame. It is used to estimate the amount of radiation to which an individual has been exposed.

Gamma ray: Electromagnetic radiation emitted from the nucleus of a radioactive atom.

Half-life: Time required for a radioactive substance to lose by decay 50 percent of its activity.

Internal radiation: Radiation produced inside the body from a radioactive substance assimilated and contained within the tissues.

Ion: Atomic particle, atom, or chemical radical (group of chemically combined atoms) bearing either a positive or negative electrical charge caused by an excess or deficiency of electrons.

Ionization: Act or result of any process by which a neutral atom or molecule acquires either a positive or negative electric charge.

Ionizing radiation: Radiation possessing sufficient energy to ionize the atoms or molecules absorbing it.

Isotope: Any of two or more forms of an element having the same atomic number (nuclear charge) and hence occupying the same position in the periodic table. All isotopes of an element are identical in chemical behavior but are distinguishable by small differences in atomic weight. The nuclei of all isotopes of an element have the same number of protons but differ in the number of neutrons.

LD₅₀: The dose of radiation which will cause death to approximately 50 percent of the members of a given animal species, usually within 30 days; the median lethal dose of radiation.

Mass unit: Unit of mass which is $\frac{1}{16}$ the mass of an oxygen atom taken as 16.00000.

Maximum permissible dose: The maximum dose of ionizing radiation that, in the light of the present knowledge, is not expected to cause appreciable bodily injury to a person at any time during his life.

Microcurie: A millionth of a curie; the quantity of any radioactive substance in which the number of disintegrations per second is 37,000.

Millicurie: A thousandth of a curie.

Neutron: Nuclear particle which is electrically neutral. Its mass is approximately the same as that of a proton.

Nuclear reactor: A device or machine for producing energy by fission or fusion of atomic nuclei.

Permissible dose: A dose of ionizing radiation that, in the light of present knowledge, is not expected to cause appreciable bodily injury to a person in any time during his life.

Proton: Nuclear particle with a positive electric charge equal numerically to the charge of the electron. Its mass is 1.007575 mass units.

Radiation sickness: The group of symptoms developed consequent to an overexposure to ionizing

radiation. The symptoms include weakness, nausea, vomiting, diarrhea, leukocytopenia, anemia, and spontaneous bleeding.

Radioactivity: Characteristic of certain kinds of matter, the atomic nuclei of which are unstable and undergo spontaneous disintegration with liberation of energy. The disintegration process, which usually results in the formation of new elements, is accompanied by the emission of one or more types of radiation, such as alpha particles, beta particles, and gamma rays.

Radiosotope: A radioactive isotope.

Radiological health: The public health aspects of the use of ionizing radiation.

SD₅₀: The dose of radiation which will cause radiation sickness to approximately 50 percent of the members of a given animal species.

Approval Withdrawn for Three Food Dyes

The Food and Drug Administration has removed three widely used coal tar dyes from the certification list of approved coloring materials which may be added to food. The law requires that food colors be certified as completely harmless.

The three colors involved, FD & C Orange No. 1, Orange No. 2, and Red No. 32, are harmless in the amounts ordinarily consumed in foods, but recent scientific investigation shows they are not harmless when taken in large amounts.

Orange No. 1 has been widely used in candy, cakes, cookies, carbonated beverages, desserts, and meat products, especially frankfurters. Orange No. 2 and Red No. 32 have been used in coloring the outer skin of oranges.

While manufacturers may no longer label and sell these three colors for food use, all three colors have been added to the list that may be certified for external drug and cosmetic use.

These colors will no longer be certified for internal use after February 14, 1956. The law does not prevent use of stocks previously certified.

Tuberculosis Morbidity and Mortality Facts and Trends

By ROBERT J. ANDERSON, M.D.

THE IMPACT of tuberculosis on our population has undergone remarkable changes in the recent past. Deaths from tuberculosis continue to decline, and illness is somewhat less frequent and of shorter duration. Current facts and trends may make clear some of the directions effort must take to accomplish a continuing control of tuberculosis.

The complexity of morbidity reporting limits good detailed data on the subject to recent years. Mortality data, however, being simpler to collect if not as rich in meaning, are available in much longer series and much more detail.

The number of deaths (fig. 1) from tuberculosis has declined between 15 percent and 20 percent each year for the last few years. In spite of this decline, provisional tabulations show that for 1954 there were 17,000 deaths from tuberculosis in the United States, a rate of 10.5 per 100,000 population. For the first quarter of 1955, the decline appears to be somewhat retarded, with a death rate about 10 percent less than that in the first quarter of 1954.

Deaths measure only one aspect, though an important one, of the impact of tuberculosis upon our population. The death rate has never

been a precise index of the trend of the tuberculosis problem, and today its usefulness is more limited than in former years. But, in recognizing the limitations of mortality as an index of trends, its usefulness as an indication of the relative influence of the disease on various population groups should not be ignored.

The number of new cases reported now constitutes one of the best indexes of the trend of tuberculosis although a decade ago reporting was so inadequate in many places as to make this measure virtually useless. In the last several years there has been approximately a 3 percent decline in the number of new cases reported per year. At this rate, more than a quarter century will be required to equal the same percent reduction realized in mortality in the last 5 years alone. The prospect of even this achievement is beclouded by one recent observation. Preliminary morbidity reports for the first 3 or 4 months of 1955 from two-thirds of the United States show an increase of 2 percent in new tuberculosis cases. A portion of this increase may be due to additional case finding. There is need for further study to determine whether there are other reasons for the increase.

Dr. Anderson, assistant chief for operational research, Division of Special Health Services, Public Health Service, presented this paper at the annual meeting of the National Tuberculosis Association, held at Milwaukee, May 26, 1955.

Tuberculous Meningitis

Tuberculous meningitis, not to be compared with respiratory tuberculosis in the number of lives it has taken, has nevertheless been an important index of the degree of control of the

whole tuberculosis problem. A low tuberculous meningitis death rate has been considered an index of success in preventing the spread of the tubercle bacillus. Two-thirds of such deaths occur among children under 15. From 1900 to 1920, there was little decline in tuberculous meningitis death rates. From 1920 to 1940, the drop was almost precipitous, as compared with the gradual decline in respiratory tuberculosis rates. This was about the time when the number of tuberculosis beds began to climb. It was a matter of considerable concern that from 1944 to 1950 there was a leveling off in the number of deaths due to tuberculous meningitis. Fortunately, there has been a substantial decline in the last 3 years, doubtless because of improved techniques of present-day drug therapy.

Now that the case-fatality rate for tuberculous meningitis has been dramatically reduced, this death rate is no longer a useful index of the adequacy of a tuberculosis control program. Accurate data on the incidence of tuberculous meningitis, however, would still be a useful index for that purpose.

Age, Sex, and Race

Tuberculosis as a disease is still very much a foe of young adults (fig. 2). Although the rate is low in children, it rises sharply in the 15- to 24-year age group and continues to increase gradually with age. For the entire United States half of the newly reported active cases are patients under 42 years of age. Thus the frequency of the disease among young adults who respond very favorably to present-day drug

Figure 1. Newly reported tuberculosis cases and tuberculosis deaths, United States, 1930-54.

Figure 2. Age-specific rates for newly reported active and probably active tuberculosis cases and tuberculosis deaths, United States, 1953.

Figure 3. Active tuberculosis cases per 1,000 X-rays taken in communitywide and hospital admission X-ray programs.

therapy is a matter of significance for tuberculosis program planning.

While a large proportion of all tuberculosis cases are reported among the younger part of our population, the case rates are higher in the older age groups. Moreover, the rates of newly reported tuberculosis cases for older people show little decline from year to year. In fact, in the age 65 and over group, a slight increase was shown for 1953. High morbidity rates for those in the older age groups are also found in communitywide surveys and in hospital admissions X-ray screening programs (fig. 3).

In the past half century (fig. 4) the decline in tuberculosis mortality by age has been most marked in infants under 1 year of age. In the first decade of the century, infants under 1 year of age had a higher tuberculosis death rate than

Tuberculosis Morbidity and Mortality

Facts and Trends

By ROBERT J. ANDERSON, M.D.

THE IMPACT of tuberculosis on our population has undergone remarkable changes in the recent past. Deaths from tuberculosis continue to decline, and illness is somewhat less frequent and of shorter duration. Current facts and trends may make clear some of the directions effort must take to accomplish a continuing control of tuberculosis.

The complexity of morbidity reporting limits good detailed data on the subject to recent years. Mortality data, however, being simpler to collect if not as rich in meaning, are available in much longer series and much more detail.

The number of deaths (fig. 1) from tuberculosis has declined between 15 percent and 20 percent each year for the last few years. In spite of this decline, provisional tabulations show that for 1954 there were 17,000 deaths from tuberculosis in the United States, a rate of 10.5 per 100,000 population. For the first quarter of 1955, the decline appears to be somewhat retarded, with a death rate about 10 percent less than that in the first quarter of 1954.

Deaths measure only one aspect, though an important one, of the impact of tuberculosis upon our population. The death rate has never

been a precise index of the trend of the tuberculosis problem, and today its usefulness is more limited than in former years. But, in recognizing the limitations of mortality as an index of trends, its usefulness as an indication of the relative influence of the disease on various population groups should not be ignored.

The number of new cases reported now constitutes one of the best indexes of the trend of tuberculosis although a decade ago reporting was so inadequate in many places as to make this measure virtually useless. In the last several years there has been approximately a 3 percent decline in the number of new cases reported per year. At this rate, more than a quarter century will be required to equal the same percent reduction realized in mortality in the last 5 years alone. The prospect of even this achievement is beclouded by one recent observation. Preliminary morbidity reports for the first 3 or 4 months of 1955 from two-thirds of the United States show an increase of 2 percent in new tuberculosis cases. A portion of this increase may be due to additional case finding. There is need for further study to determine whether there are other reasons for the increase.

Dr. Anderson, assistant chief for operational research, Division of Special Health Services, Public Health Service, presented this paper at the annual meeting of the National Tuberculosis Association, held at Milwaukee, May 26, 1955.

Tuberculous Meningitis

Tuberculous meningitis, not to be compared with respiratory tuberculosis in the number of lives it has taken, has nevertheless been an important index of the degree of control of the

whole tuberculosis problem. A low tuberculous meningitis death rate has been considered an index of success in preventing the spread of the tubercle bacillus. Two-thirds of such deaths occur among children under 15. From 1900 to 1920, there was little decline in tuberculous meningitis death rates. From 1920 to 1940, the drop was almost precipitous, as compared with the gradual decline in respiratory tuberculosis rates. This was about the time when the number of tuberculosis beds began to climb. It was a matter of considerable concern that from 1944 to 1950 there was a leveling off in the number of deaths due to tuberculous meningitis. Fortunately, there has been a substantial decline in the last 3 years, doubtless because of improved techniques of present-day drug therapy.

Now that the case-fatality rate for tuberculous meningitis has been dramatically reduced, this death rate is no longer a useful index of the adequacy of a tuberculosis control program. Accurate data on the incidence of tuberculous meningitis, however, would still be a useful index for that purpose.

Age, Sex, and Race

Tuberculosis as a disease is still very much a foe of young adults (fig. 2). Although the rate is low in children, it rises sharply in the 15- to 24-year age group and continues to increase gradually with age. For the entire United States half of the newly reported active cases are patients under 42 years of age. Thus the frequency of the disease among young adults who respond very favorably to present-day drug

Figure 1. Newly reported tuberculosis cases and tuberculosis deaths, United States, 1930-54.

Figure 2. Age-specific rates for newly reported active and probably active tuberculosis cases and tuberculosis deaths, United States, 1953.

Figure 3. Active tuberculosis cases per 1,000 X-rays taken in communitywide and hospital admission X-ray programs.

therapy is a matter of significance for tuberculosis program planning.

While a large proportion of all tuberculosis cases are reported among the younger part of our population, the case rates are higher in the older age groups. Moreover, the rates of newly reported tuberculosis cases for older people show little decline from year to year. In fact, in the age 65 and over group, a slight increase was shown for 1953. High morbidity rates for those in the older age groups are also found in communitywide surveys and in hospital admissions X-ray screening programs (fig. 3).

In the past half century (fig. 4) the decline in tuberculosis mortality by age has been most marked in infants under 1 year of age. In the first decade of the century, infants under 1 year of age had a higher tuberculosis death rate than

Tuberculosis Morbidity and Mortality

Facts and Trends

By ROBERT J. ANDERSON, M.D.

THE IMPACT of tuberculosis on our population has undergone remarkable changes in the recent past. Deaths from tuberculosis continue to decline, and illness is somewhat less frequent and of shorter duration. Current facts and trends may make clear some of the directions effort must take to accomplish a continuing control of tuberculosis.

The complexity of morbidity reporting limits good detailed data on the subject to recent years. Mortality data, however, being simpler to collect if not as rich in meaning, are available in much longer series and much more detail.

The number of deaths (fig. 1) from tuberculosis has declined between 15 percent and 20 percent each year for the last few years. In spite of this decline, provisional tabulations show that for 1954 there were 17,000 deaths from tuberculosis in the United States, a rate of 10.5 per 100,000 population. For the first quarter of 1955, the decline appears to be somewhat retarded, with a death rate about 10 percent less than that in the first quarter of 1954.

Deaths measure only one aspect, though an important one, of the impact of tuberculosis upon our population. The death rate has never

been a precise index of the trend of the tuberculosis problem, and today its usefulness is more limited than in former years. But, in recognizing the limitations of mortality as an index of trends, its usefulness as an indication of the relative influence of the disease on various population groups should not be ignored.

The number of new cases reported now constitutes one of the best indexes of the trend of tuberculosis although a decade ago reporting was so inadequate in many places as to make this measure virtually useless. In the last several years there has been approximately a 3 percent decline in the number of new cases reported per year. At this rate, more than a quarter century will be required to equal the same percent reduction realized in mortality in the last 5 years alone. The prospect of even this achievement is beclouded by one recent observation. Preliminary morbidity reports for the first 3 or 4 months of 1955 from two-thirds of the United States show an increase of 2 percent in new tuberculosis cases. A portion of this increase may be due to additional case finding. There is need for further study to determine whether there are other reasons for the increase.

Dr. Anderson, assistant chief for operational research, Division of Special Health Services, Public Health Service, presented this paper at the annual meeting of the National Tuberculosis Association, held at Milwaukee, May 26, 1955.

Tuberculous Meningitis

Tuberculous meningitis, not to be compared with respiratory tuberculosis in the number of lives it has taken, has nevertheless been an important index of the degree of control of the

economic status is examined, this relationship is not so marked. For example, in a study made in Cleveland, Ohio, it was learned that tuberculosis mortality was almost 20 times as great in the lowest economic group as in the highest (fig. 8). However, previously unknown tuberculosis cases in the lowest economic group were only about 1.5 times as great as in the highest. It seems reasonable, therefore, to conclude that low economic status and tuberculosis each tend to beget the other.

This suggests the need for study of the social, psychological, economic, and nutritional factors which have been recognized as being important in the development of tuberculosis. It also suggests the need for directing case-finding activities. It is not sufficient to search for cases among the population groups which have the highest death rates. It is better to search among the groups with the highest prevalence rates, but undue emphasis may result in missing the large number of cases in those groups that have lower prevalence rates but large numbers of people.

Geographic Distribution

Tuberculosis death rates generally are high in the large cities. Cities of 100,000 population and over have a tuberculosis death rate approximately 80 percent higher than that of the remainder of the country. In fact, when the death rates for each State, exclusive of the large cities, are computed, there are only four States—Arizona, Tennessee, Arkansas, and Kentucky—which have death rates higher than the average

rate for the large cities. Maryland is one of the States with a fairly high tuberculosis death rate, yet, when Baltimore is excluded, its death rate in 1953 was below 10 per 100,000 population. Maryland exclusive of Baltimore has a lower rate than do any of the States nearby with their large cities excluded. When the large cities in Michigan, Wisconsin, and Minnesota are excluded, those States compare quite favorably with the other middle western States and the Mountain States exclusive of large cities. People who live in the suburbs have a death rate less than half the rates in the large cities. Small cities, unincorporated urban areas, and rural areas have the lowest rates.

Morbidity rates are lowest in some of the States in the western plains and Rocky Mountains. A fairly close parallel exists between reported cases and deaths by States (figs. 9 and 10). The decline in mortality has been without any apparent geographic pattern (fig. 11). Some States which had low tuberculosis death rates in 1947 also had the least percentage decline, while other States with moderately low death rates showed the greatest improvement. A similar variation in decline occurred in the group of States with high death rates.

Case Finding and Reporting

The relative slowness with which the rate of newly reported cases has declined has been the object of considerable curiosity. Reporting was very inadequate in many States before 1947, and during the period 1947 to 1949 morbidity reporting was inflated by the inclusion of cases of borderline clinical significance. For recent years, however, rates of newly reported cases are generally not inflated. The evidence for this is twofold: First, approximately 37 percent of new active cases had positive sputum at the time of report; second, 78 percent of the cases were reported as either moderately advanced or far advanced. There is no appreciable change from the preceding decade.

Further evidence of the persistently high incidence of tuberculosis is in the number of admissions to tuberculosis hospitals. These have done little more than fluctuate in the period from 1947 to 1953 in several large States for which data are available. Vacancies in beds are

Figure 8. Percentage distribution of deaths from tuberculosis, known cases and previously unknown cases, by economic fifth, Cuyahoga County, Ohio.

any other age group. In recent years this group has had a lower death rate than has any of the adult age groups.

From 1930 to 1950, there was relatively little drop in tuberculosis death rates in the older age groups, but in the last few years, the decline has been quite marked. Even more rapid has been the decline in death rates for those under 25.

Rates of newly reported active cases of tuberculosis by sex and race continue to demonstrate somewhat the same pattern as in former years. Rates for white males are approximately twice those for white females. Rates for nonwhites are approximately three times as high as for whites. Yet, in six States, the tuberculosis case rates are higher for white males than for nonwhite females, and further, the number of cases reported for white males (fig. 5) is almost as great as the number for the other three groups combined.

The proportionate decline in death rates has been much greater in recent years among fe-

Figure 4. Age-specific tuberculosis death rates, United States, 1900-1953.

Figure 5. Race and sex of newly reported active and probably active tuberculosis cases, United States, 1953.

Figure 6. Race and sex-specific tuberculosis death rates, United States, 1940-54.

Figure 7. Marital status, age-specific tuberculosis death rates for white males, United States, 1949-51 average.

males than among males (fig. 6). If this trend continues for another 5 years, white males will have a higher tuberculosis death rate than nonwhite females.

Marital and Economic Status

Generally, death rates from all causes are definitely higher for the unattached than for the married (fig. 7). Tuberculosis death rates are much higher for single, widowed, and divorced people than for married persons.

The close relationship between tuberculosis mortality and economic status has been generally recognized. However, when the prevalence of unreported tuberculosis in terms of

Figure 12. The age groups with the most tuberculosis not reached in communitywide chest X-ray surveys.

leaves a fine line between minimal and moderately advanced disease.

With the emphasis upon reporting active and probably active cases, there is a built-in bias against the reporting of minimal tuberculosis cases. From a practical viewpoint, treatment is not recommended for the minimal inactive cases.

In spite of the difficulties of diagnosing tuberculosis before it has extended, it is still the responsibility of tuberculosis control workers to put forth all possible efforts to use effectively the presently available means for diagnosis. For example, communitywide surveys and other X-ray case-finding programs have generally been successful in the various States, and many millions of people have been X-rayed. However, the surveys have not been as successful as might have been hoped (fig. 12). The older age groups in which the rate of active tuberculosis is greatest have not been adequately covered.

Prevalence

Current information indicates that there are somewhat less than 400,000 active tuberculosis cases in the United States at any one time, approximately one-third of which are hospitalized for tuberculosis, one-third are known cases at home, and one-third are undetected cases.

Several studies in progress indicate that the total number of known active cases is definitely declining. How great this decline is cannot now be accurately measured; but some precise in-

formation is available concerning known tuberculosis cases hospitalized at any one time, or the beds the patients occupy. On April 1, 1954, there were 2 percent fewer patients hospitalized for tuberculosis than a year earlier. A study by the National Tuberculosis Association and the Public Health Service, in November 1954, of a large number of tuberculosis hospitals shows a further decline of 6.7 percent. However, the number of patients hospitalized for tuberculosis in November 1954 was greater than at any time prior to 1950.

The number of known active cases at home appears to be declining. Before the days of chemotherapy, the majority of patients discharged from sanatoriums continued to have active disease at home for a substantial period of time. Today, most patients discharged from the sanatorium are discharged with arrested or inactive disease. A substantial proportion of these patients continue to receive chemotherapy at home for a period of months or years after sanatorium discharge. Thus, even though the number of known active cases at home may be declining, the demands upon health department services are actually increasing. These cases, arrested but continuing on drug therapy, will actually require more public health supervision from health department staffs, public health nurses in particular, than corresponding patients received a decade ago. Current studies show a very marked inadequacy of public health supervision and treatment of the known tuberculosis cases who are at home. Although the prevalence of tuberculosis in unattached males, migrants, and other special groups presents a challenging problem, there are numerically more known tuberculosis cases at home in other categories who are not getting control services.

Infection Rates

The number of persons infected with tubercle bacilli is not known. Relatively little of the tuberculin testing now being done provides adequate information concerning infection rates. Several studies are in process and are being planned for this purpose. One such study in the District of Columbia shows an infection rate of only 3 percent for 7-year-old children of all races combined. It is certain, however, that

Figure 9. Newly reported active and probably active tuberculosis cases per 100,000 population (provisional data), United States and Territories, 1954.

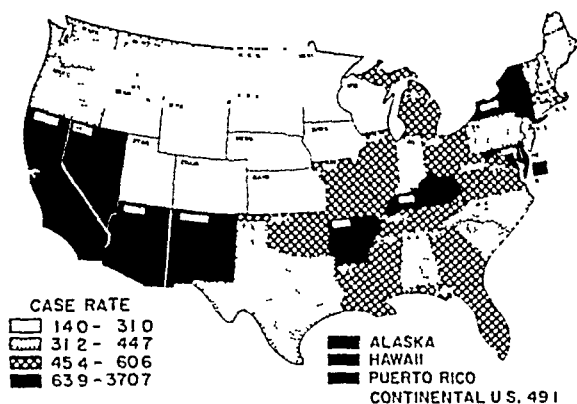

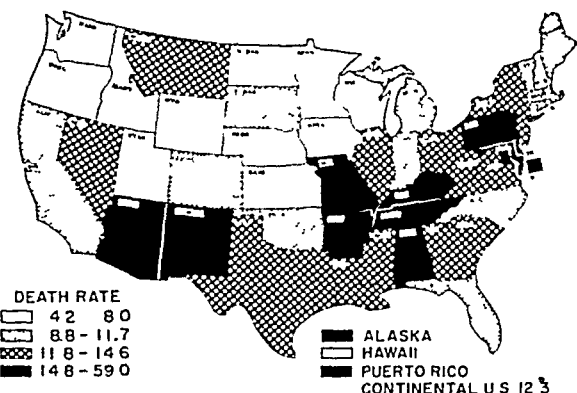

Figure 10. Tuberculosis deaths per 100,000 population, United States and Territories, 1953.

probably due more to reductions in duration of stay than to decreases in admissions.

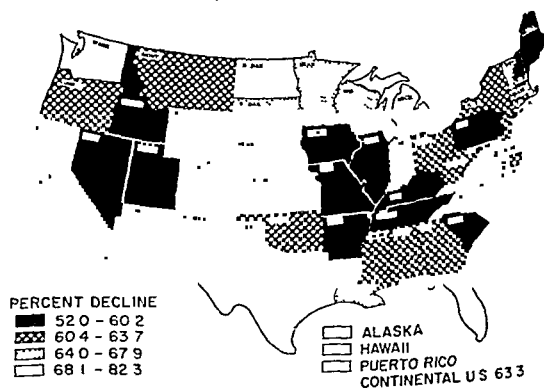

Tuberculosis case finding and reporting now are definitely superior to that of previous decades. For example, almost one-third of reported cases are found by X-ray survey. Fewer cases are first reported by death certificate. Even now, however, more than one-fourth of tuberculosis deaths were never reported as living cases. Large numbers of cases are not reported until the report of the sanatorium admission is received by the health department. The number of cases that remain unreported because they are not referred for sanatorium admission is not known. While progress has been made in reducing the proportion of cases first reported in the far-advanced stage to 37 percent,

it would seem reasonable to expect a further movement of reported cases from the far-advanced category to the moderately advanced category provided case-finding and case-reporting efforts are not relaxed.

Usually cases are diagnosed as tuberculous before they are referred for hospitalization, and in such instances the cases should be reported to the health department by some source other than the tuberculosis sanatorium. Even so, in 10 States, 40 to 60 percent of the reports of new active cases come from the sanatorium. It is at least questionable that the reporting systems in these States are adequate. In any event, the reporting of cases should be evaluated in the light of the specific practices in any given area.

To find as many cases in early stages of the disease as possible is a most worthwhile and desirable goal, but it is questionable that early case finding can be judged solely in terms of the proportion of new cases which are minimal in extent. The duration of time in which tuberculosis may progress from minimal to advanced may be very short, and present-day diagnostic procedures are such that it is difficult to discover active cases before they become moderately advanced. In order to prove tuberculosis by demonstration of tubercle bacilli from sputum, or gastric or bronchial lavage, necrosis of the lung must have set in, which means that a cavity is being formed. When a cavity can be seen on an X-ray, the case is no longer minimal in extent but must be classified at least as moderately advanced. Obviously, this frequently

Threshold Limit Values for 1955

Values are given in the following tabulation for the maximum average atmospheric concentration of contaminants to which workers may be exposed for an 8-hour working day without injury to health.

These values are based on the best available information from industrial experience, from experimental studies, and, when possible, from a combination of the two. They are not fixed values but are reviewed annually by the Committee on Threshold Limits of the American

Members of the Committee on Threshold Limits of the American Conference of Governmental Industrial Hygienists are: Allan L. Coleman, chairman, William L. Ball, L. T. Fairhall, Kingsley Kay, H. E. Stokinger, A. J. Vorwald, and Louis F. Weller.

Conference of Governmental Industrial Hygienists for changes, revisions, or additions as further information becomes available. Threshold limits should be used as guides in the control of health hazards and should not be regarded as fine lines between safe and dangerous concentrations. They represent conditions only within which it is felt that workers may be repeatedly exposed, day after day, without their health being adversely affected. It is felt, at the present time, that workers should not be exposed to a working environment containing any of these substances in excess of the value indicated.

These values are not intended for use, or for modification for use, in the evaluation or control of community air pollution or air pollution nuisances.

there are millions of individuals in the United States today, possibly 50 million, who are infected with tubercle bacilli. It is necessary, however, to learn more about the changes which are occurring in new tuberculous infections in the many social, biological, and geographic segments of our population.

Looking Forward

It is hazardous to risk predictions of trends in any field, particularly in tuberculosis. Yet the future is a lure difficult to resist. So marked has been the decline in the death rate of tuberculosis in the past 10 years that to many its disappearance as a public health problem seems an eventuality of an immediate tomorrow. Such optimism is a trap into which even the most guarded minds have fallen, and from them frequently comes the question, "How much longer shall we continue to exert tuberculosis control efforts?"

Despite the unreality of setting an end point for tuberculosis as a public health challenge, an intermediate goal can arbitrarily be selected for the sake of argument, and time limits can be drawn to emphasize the continuing magnitude of the problem.

Even in terms of death rates alone the future

task is large and prolonged. It will require years of effort to achieve a death rate of only 1.5 per 100,000 population, which is about the current death rate from acute rheumatic fever, appendicitis, arthritis, poliomyelitis, and several other diseases which are still considered to be of public health import. The maternal mortality rate is about at that level. Measles, whooping cough, and infectious hepatitis combined do not exceed it. When the death rate from tuberculosis drops to the level of these important diseases, then tuberculosis control programs and needs should be reexamined.

Indeed, if conditions remain the same, and if control activities are so maintained that the rate of decline in mortality will equal that of the past 5 years:

It will be 11 years before the crude tuberculosis death rate is 1.5 per 100,000 population; 7 years before this death rate is achieved for white females; between 10 and 15 years, for non-white males and females, and white males; and 25 years before the age group over 65 has a death rate of 1.5 per 100,000 population.

The task of defeating tuberculosis is plainly not done. Persisting cases of tuberculosis, especially those out of hospitals, challenge every ingenuity in planning the content and scope of control programs of tomorrow.

Armed Services Medical and Dental Symposium

A 3-day symposium, sponsored by the First Naval District, Boston, Mass., on developments in military medicine and dentistry with special emphasis on atomic warfare, special weapons, and isotopes has been scheduled for March 21-23, 1956.

The first meeting will be held at the United States Naval Hospital, Chelsea, Mass. On the mornings of the second and third days, clinics will be scheduled at various hospitals in Boston on the treatment of disease with radioactive isotopes. Afternoon lectures will be given at the Jimmy Fund Foundation Building and at the New England Deaconess Hospital.

Programs and additional information may be obtained from the District Medical Officer, First Naval District, 495 Summer Street, Boston 10, Mass.

TENTATIVE THRESHOLD LIMIT VALUES

The following values are suggested for further consideration before being presented for adoption as established values. (An asterisk * marks materials added in 1955 and for which bibliographical material has been prepared. The other materials appeared in the 1954 report.) It is proposed that the entire list will be presented for adoption at the meeting of the American Conference of Governmental Indus-

trial Hygienists in 1956, if no reason to the contrary is forthcoming.

Reference material has been prepared on each of the following substances and, though in some instances it is rather meager, it is available for distribution. The committee welcomes suggestions of substances to be added and also comments, additional references, or reports of experience with these materials.

Aldrin (1,2,3,4,10,10-hexachloro-1,4,4a,5,8,8a-hexahydro-1,4,5,8-dimethanonaphthalene)-----	0.25	mg/M ³

(V ₂ O ₅ fume)-----	0.1	mg/M ³
Zirconium-----	5	mg/M ³

BERYLLIUM: During the past few years, several papers have reported a limit of 2γ per cubic meter of air for beryllium. Among these is the paper by Van Ordstrand, H. S.: Berylliosis, A. M. A. Arch. Indust. Hyg. 10: 232-234, September 1954, and one by Sterner, J. H., and Eisenbud, M.: Epidemiology of Beryllium

Intoxication, A. M. A. Arch. Indust. Hyg. 4: 123-151, August 1951. Conflicting data from industrial experience have caused the committee to postpone the suggestion of a threshold limit for this material. It is apparent that more epidemiological work is needed for the establishment of a definite view.

special inventory form, which the Public Health Service made available to State health departments in 1950. The form, prepared with the assistance of the American Public Works Association and various individuals, had been designed to facilitate uniform collection of refuse-handling data. The rest of the data were secured from published reports of other surveys conducted during the inventory period by State health departments or other agencies concerned with refuse handling.

The data presented in this report must be interpreted with cognizance of two limitations. First, although data were received from 30 States, 98 percent of the cities surveyed were in 17 States located east of the Rocky Mountains. Second, certain of the communities reported on early in the inventory period undoubtedly had changed their practices by 1954. Nevertheless, the information presented may provide assistance in evaluating refuse-sanitation practices in the United States.

The data collected during the course of the inventory show encouraging trends, but they also indicate that, despite the long-standing problem of disposing of municipal solid wastes, the preponderance of the job still remains to be accomplished.

Regulations

Three hundred forty-two cities reported that they had regulations governing one or more of the three phases of refuse handling, namely, storage, collection, or disposal. However, because of the nature of the data on the remaining 931 cities, it was not possible to establish what percentage of the latter actually did not have regulations on refuse handling.

Of the 342 cities, 53 percent had regulations which governed all 3 phases. Twenty-two percent had regulations governing storage only, and another 10 percent had regulations covering storage and either collection or disposal. The remaining 15 percent had regulations controlling collection only, disposal only, or both of these.

Data on the enforcement of regulations were received from 260 cities. Fifty-three (20 percent) of these reported that the regulations were enforced by the police department; 34

Definition of Terms

Refuse: All putrescible and nonputrescible solid wastes (except body wastes), including garbage, rubbish, ashes, street cleanings, dead animals, abandoned automobiles, and solid market and industrial wastes.

Garbage: Putrescible animal and vegetable wastes resulting from the handling, preparation, cooking, and consumption of food.

Ashes: The residue from the burning of wood, coal, coke, or other combustible materials.

Rubbish: Nonputrescible solid wastes (except ashes), consisting of both combustible and noncombustible wastes, such as paper, cardboard, cans, grass and shrubbery clippings, wood, glass, bedding, and crockery.

(13 percent), by the public works department or the agency responsible for the collection of refuse; 40 (15 percent), by the health department; and 72 (28 percent) reported that enforcement was the joint responsibility of the health department and some other municipal department, such as the police or public works department. (The remaining 61 cities did not specify the enforcement agency.)

Storage Practice

Separation requirements. Data on separation requirements were received for 1,244 cities. In 488 (39 percent) complete separation of garbage, rubbish, and ashes was required. Combined storage of all refuse was permitted by 642 (52 percent), and 98 (8 percent) required only the separation of garbage from other refuse. Other requirements, such as separation of combustibles from noncombustibles, were reported by 16 cities (1 percent).

Types of containers. Data concerning the use of covered metal containers for storing refuse are given in table 1. It is encouraging to note that for garbage or refuse containing garbage about 85 percent of the reporting cities required the use of this type of container.

Size of containers. Of the 95 cities reporting on the size of containers used for storing resi-

A summary report on refuse storage, collection, and disposal practices in 1,273 cities in 30 States, 1951-54.

Refuse Handling Practices in the United States

By MALCOLM C. HOPE, M.S., M.P.H., CHARLES C. JOHNSON, Jr., B.S.
and LEO WEAVER, B.C.E.

THE sanitary storage, collection, and disposal of municipal refuse have been a community problem, in varying degrees, since men first banded together for protection. It is only in recent years, however, that the problem has begun to receive concerted attention and action.

Studies have shown that the sanitary handling of refuse is an important factor in controlling such disease vectors as rats, flies, and mosquitoes. The feeding of raw garbage to hogs has been shown to be not only an important factor in the chain of transmission of trichinosis to man, but also a primary mode of transmission of virus diseases of swine, such as vesicular ex-

anthema. In certain metropolitan areas, disposal of refuse by burning in backyard or apartment-house incinerators has been singled out as a significant source of air pollution. The National Fire Protection Association has reported data indicating that in 1953 "rubbish, ignition unknown" ranked third among 26 known causes of fires in buildings. Furthermore, the public is becoming impatient with the nuisances and inconveniences fostered by inadequate and insanitary refuse-handling systems.

So that the extent of the refuse-handling problem might be better understood and the job which yet needs to be done planned accordingly, the Public Health Service has made an inventory of municipal refuse storage, collection, and disposal practices. During the period 1951 through 1954, data outlining practices of 1,273 cities in 30 States were obtained. These data are summarized in this report. Distribution of the cities according to population group is shown in the following tabulation:

Mr. Hope is chief of the General Engineering Program, Division of Sanitary Engineering Services, Public Health Service. Mr. Johnson and Mr. Weaver are staff engineers in that program.

The inventory reported in this paper was initiated and carried on under the supervision of Ralph J. Van Derwerker and Eugene L. Lehr when they were with the Division of Sanitary Engineering Services. Mr. Van Derwerker is chief sanitary engineer officer of the United States Coast Guard, and Mr. Lehr is assistant chief, Sanitation Services Branch, Division of Indian Health, Public Health Service.

William Xanten, superintendent of sanitation of Washington, D. C., and William Foster, engineering editor of the American City Magazine, among others, assisted in preparing the inventory form.

Population group	Number of cities
1,000-4,999	765
5,000-9,999	237
10,000-24,999	160
25,000-49,999	55
50,000-99,999	23
100,000 or more	30
Unknown	3

Most of the data included in this inventory were collected by or through State health departments. These data were reported on a

Table 3. Frequency of refuse collection in residential areas

Class of refuse	Summer collection					Winter collection				
	Number of cities reporting	Less than 1 per week	1 per week	2 per week	More than 2 per week	Number of cities reporting	Less than 1 per week	1 per week	2 per week	More than 2 per week

Ashes.....						16	3	4	3	6
Combined refuse..	387	27	60	93	207	387	26	71	85	201

Types of vehicles. Data on the types of vehicles used in collecting refuse were received from 337 cities having municipal collection. Of these, 157 (46 percent) relied on open vehicles for the collection of refuse. About 10 percent reported the use of covered vehicles, and another 10 percent, mechanical-compactor-type vehicles. The remaining 34 percent reported the use of combinations of these types of vehicles.

Data from 82 cities using contract collection showed that 49 (60 percent) used open vehicles. Only 12 (15 percent) reported the use of the mechanical-compactor type either exclusively or in combination with other types. Data from 147 cities having private collection arrange-

ments revealed that 111 (75 percent) relied on open vehicles. Only 11 (10 percent) reported the use of the mechanical-compactor type either exclusively or in combination with other types.

Method of financing. Table 7 lists the data reported on the method of financing refuse collections. Of the 633 cities that specified their method of financing, 382 (60 percent) indicated that they relied solely on the fee system. An additional 50 (8 percent) reported the use of both special fees and the general tax fund. An analysis of the data by population group revealed that of the communities in the 1,000-4,999 category 75 percent relied wholly or in part on the fee system; of those in the 5,000-9,999 category, 62 percent; of those in the 10,000-24,999 group, 63 percent; of those in the 25,000-49,999 category, 48 percent; of those in the 50,000-99,999 category, 34 percent; and of the cities with 100,000 or more population, 39 percent.

Miscellaneous data. Of 561 cities providing information on the private collection of garbage for hog feed, 464 (83 percent) specified that they permitted this practice. However, during the period of this inventory, many communities

Table 1. Percentage of reporting cities requiring covered metal storage containers

Class of refuse	Residential		Commercial	
	Number cities re- porting	Percent requiring covered metal containers	Number of cities re- porting	Percent requiring covered metal containers
Garbage-----	138	83	119	81
Rubbish-----	26	58	14	50
Ashes-----	8	25	6	33
Combined refuse-----	171	87	131	86

dential garbage, only 12 (13 percent) permitted storage in containers larger than 30 gallons. Where combined storage of refuse was practiced, however, 43 (36 percent) of the 118 reporting cities permitted containers larger than 30 gallons. Table 2 shows the residential container-size requirements reported for each class of refuse.

Data on the size of containers used for commercial garbage from 69 cities showed that 28 (41 percent) required that containers be of 30 gallons or less. Thirty-two (46 percent) allowed the use of containers up to 40 gallons in size, and 9 (13 percent) permitted storage in containers larger than 40 gallons. Where combined storage of refuse was permitted, 57 of 98 cities required that containers be of 30 gallons or less, the remainder permitting the use of containers larger than 30 gallons in capacity.

Collection Practice

Frequency of collection. Tables 3 and 4 show the variations in the frequency of collection for the various classes of refuse according to season of the year. Of the 698 cities reporting on the summer collection of garbage or combined refuse in residential areas, 397 (57 percent) made collections at least twice a week. With respect to summer collection from commercial establishments, 352 (52 percent) of 626 cities reported that garbage or refuse containing garbage was collected daily. An additional 138 (29 percent) collected this material at least twice a week.

As might be presumed, during the winter

fewer cities provided twice-a-week collection. However, 646 (93 percent) of the 691 cities reporting on winter collection of garbage or combined refuse in residential areas provided at least once-a-week pickup of this material.

Point of collection. Information was obtained from 448 cities on the point at which the collection crew was authorized to pick up refuse. As shown in table 5, 190 (43 percent) specified either the curb or the alley, or both, as the pickup point. Two hundred one (45 percent) reported various combinations of curb, alley, front houseline, and rear houseline as being acceptable pickup points.

Responsibility for collection. In table 6 are the data concerning the agencies responsible for the collection of municipal refuse. It is interesting to note that, when each class of refuse is considered separately, there is a similarity between commercial and residential responsibilities. The responsibility for collection of garbage is fairly evenly distributed on a municipal, contract, and private basis.

Combined collection of refuse in more than 50 percent of the communities was accomplished by private or individual arrangements. Analysis of the data showed that 373 of the 393 cities (95 percent) reporting private residential collection were in the 1,000-9,999 population group. On the other hand, only 20 of 112 cities (18 percent) having a population of 10,000 or more utilized private collection, and 79 (68 percent) utilized municipal collection. A similar relationship between population and responsibility for collection was found upon analysis of the data on combined collection of refuse in commercial areas.

Table 2. Size of containers for residential refuse

Class of refuse	Number of cities reporting	Number reporting maximum size of—			Number allowing more than 30 gallons
		Less than 10 gallons	10-19 gallons	20-30 gallons

Rubbish----	22	0	2	10	10
Ashes-----	9	1	2	4	2
Combined refuse----	118	0	13	62	43

Several agencies interested in rural development pool their experience to accelerate a program to install water systems for Tennessee Valley farmers.

Combined Efforts Stimulate Development of Rural Water Systems

By C. H. WEAVER, B.S., C. T. ROBERTS, and C. M. DAVIDSON, C.E., M.P.H.

FARM WATER supplies under pressure are practically nonexistent in many localities in the southeastern United States. In the Tennessee Valley, an estimated 25 percent of rural families had such water supplies in 1953.

Since that time an accelerated rural water system program has been developed in the Tennessee Valley, based on cooperation among the various agencies concerned with the health and welfare of rural people.

Cooperating have been State and county health departments, county and home demonstration agents, vocational agriculture groups, local power systems which retail electricity, and the Tennessee Valley Authority, a Federal agency with interests in many phases of regional development.

These agencies have combined their efforts in order to (a) improve rural sanitation and health; (b) encourage more farm people to have a safe, dependable water supply; and (c) im-

prove rural living generally through the many improvements that running water under pressure makes possible.

The present cooperative program is based on ideas developed by the Mississippi State Board of Health through an experience in Winston County, Miss., and by the TVA in the Chestuee watershed area of eastern Tennessee.

The Chestuee Experience

A low percentage of the 854 farms in the Chestuee area had pressure water systems when a program to inform the farm people about the advantages of safe and dependable water supplies was initiated. TVA agricultural and sanitary engineers, working with county agents in three counties and with health department sanitarians, called on farmers to discuss water supply, taking along demonstration electric pump equipment.

Then the county sanitarians and TVA agricultural engineers held four rural community water systems demonstrations on farms where water systems were actually being installed. Sanitarians planned the well location and the waste disposal system. Agricultural engineers assisted with technical data on pump size and other factors. Together they showed the farmers how to install a pressure water system which would assure an adequate safe supply of water.

Mr. Weaver is electrical development supervisor, Mississippi district, Tennessee Valley Authority, Tupelo, Miss. Mr. Roberts is field advisory sanitation supervisor for the Mississippi State Board of Health, Jackson, Miss., and Mr. Davidson is chief, Environmental Hygiene Branch, Division of Health and Safety of the Tennessee Valley Authority.

Table 6. Responsibility for collection of refuse

undoubtedly experienced considerable change in the methods by which agencies or individuals arranged to handle garbage ordinarily fed to swine. In 1952, the feeding of raw garbage to swine was shown to be a primary cause of the widespread outbreak of the virus disease of swine, vesicular exanthema, which occurred in that year. By 1955, all but two States had regulations requiring the disinfection of garbage fed to swine. The United States Department of Agriculture reported that as of June 30, 1955, 83 percent of almost 1½ million garbage-fed swine on more than 13,000 garbage-feeding establishments were fed cooked garbage.

With regard to the installation of garbage grinders, 28 of 503 reporting cities (6 percent)

prohibited the installation of these devices. Of interest was the fact that 21 of the 28 cities were in the 1,000-9,999 population category.

Of 688 cities reporting on scavenging practice (during the storage or collection period), 139 (20 percent) reported that scavenging was not permitted. Of the cities reporting that scavenging was permitted, almost 90 percent indicated that no license was required.

Disposal Practice

All 1,149 cities reporting on disposal practice indicated the use of one or more of four methods of disposal: incineration, sanitary land fill, open dump, and hog feeding. Ninety-one of the cities (8 percent) reported the use of incineration and 114 (almost 10 percent) reported the use of the sanitary land fill. Table 8 gives the number of cities, according to population category, using each of the four methods.

Table 8. Number of cities reporting use of specified methods of refuse disposal, according to population group

Population group	Number of cities reporting	Incineration	Sanitary land fill	Open dump	Hog feeding
1,000-4,999.....	667	18	32	539	159
5,000-9,999.....	221	26	24	131	80
10,000-24,999.....	156	18	19	76	73
25,000-49,999.....	53	12	16	25	21
50,000-99,999.....	20	6	11	7	8
100,000 and over.....	29	11	11	16	7
Total.....	1,149	91	114	796	348

¹ Population group not specified for 3 cities. ² Population group not specified for 1 city. ³ Population group not specified for 2 cities.

Of significance was the fact that 616 (54 percent) of the 1,149 cities reported the use of the open dump as their only means of disposal. Another 130 (11 percent) reported the use of a combination of the open dump and hog feeding as their only means of refuse disposal.

Concrete is utilized in Monroe County, Miss., to protect well from surface water contamination.

If a spring is used, is it protected from surface drainage?

4. Do you own your farm? If not, whose farm do you live on?

5. Would you like someone who could give you information on these items of sanitation to visit your home?

Such a postcard questionnaire was sent out by seven power associations in northeastern Mississippi.

Of the 24,568 farm families which received these cards, 9,103, or about 37 percent, have thus far returned them. Of the families returning the cards, nearly half (4,254) have requested a visit from the health department and the power association. Home visits made total 3,480. Of these 1 out of 5 have installed pressure water systems, and 22 percent have protected their water supplies by sealing and concreting.

Now the idea has spread to rural electric systems in northern Alabama, where 2 surveys have been started, and in Tennessee, where 6 surveys are in process. These 8 surveys will reach 50,000 farm families.

To encourage rural people to return the survey cards, local pump dealers and other businessmen offered prizes. A drawing was held from the returned survey cards, this drawing often being made at a public gathering where representatives of the health department and the power association made brief talks on pressure water systems and rural sanitation. The

survey cards, in addition to giving valuable information about water supply and sanitation conditions, have presented the health department and the power associations with an invitation to visit thousands of farm homes to discuss sanitation.

Calls are made first on those persons who actually indicate on the survey card that they want a visit. Next, other persons surveyed are contacted. The general pattern has been that the county sanitarian and the power association's agricultural engineer have made the first few farm visits together. Then they have divided the remaining calls. The sanitarian is especially qualified to give advice and answer questions about rural sanitation; the agricultural engineer is trained to handle inquiries about the selection and installation of pressure water systems. But in working together each of these specialists learns much about the other's work.

Water System Workshops

After the surveys were under way, it was decided that a series of water system workshops in various parts of northeastern Mississippi would be held to give detailed information on pressure water systems and sanitation to field workers from the several interested agencies. This was essentially a matter of "teaching the teachers," since those invited included county sanitarians, other local and State health officials, vocational agriculture teachers, teachers of veterans' classes, extension service workers, county agents, and power association personnel.

Those making talks included agricultural engineers from power associations and TVA, representatives of the health departments, the extension service, and the agricultural education department.

In addition to lectures, there were demonstrations to teach the agricultural and health workers as much as possible about running water on the farm. At each meeting there were trailers equipped with different types of electric pumps. The pumps had moving parts exposed so their operation could be easily explained. Other equipment included a telescoping tower which was used to demonstrate the effect of elevation on pump efficiency. By raising a pump

Later, a 1954 survey showed that 250 farms, 30 percent of the total, had pressure water systems. Another 143 farm families said they wanted such systems soon. From the Chestuee experience, these two ideas were gained:

1. Cooperation among several groups interested in rural water supply, particularly health departments and local power systems, is the key to effective work in this field.

2. Personal calls on farmers are particularly successful in encouraging utilization of safe, adequate water supplies.

Winston County Experience

In the spring of 1954, the sanitarian of Winston County, Miss., with the aid of the Mississippi State Board of Health, conducted a rural sanitation survey in his county. The survey was aimed at obtaining general information about water supply, excreta disposal, and screening of doors and windows. The sanitarian used the Agricultural Stabilization Committee's mailing list and received 600 replies from 2,300 survey sheets sent out.

One of the questions asked was, "Do you wish the sanitation supervisor to visit your place to help you with your problems?" Three hundred seventy-five answered in the affirmative, and 380 visits were made. As a result, 112 wells were protected, 62 new pressure water systems were installed, and 102 septic tanks were installed or improved.

The Winston County survey was a success, but it proved to be too expensive for a county health department since no funds are budgeted for this type of survey in Mississippi county health departments. Too, the Agricultural Stabilization Committee's mailing list proved to be out of date.

Collective Effort in Mississippi

Early in 1954, the Mississippi State Board of Health and local health departments were developing plans for a more intensive approach to rural sanitation problems in Mississippi.

TVA's Electrical Development Branch, which works with local distributors of TVA-generated electricity, is interested in improving farm living through the improved use of elec-

tricity. TVA's Division of Health and Safety has a variety of interests directed toward the problem of rural sanitation. The rural electric power associations in northeastern Mississippi want to encourage more widespread use of pressure water systems, which in turn lead to the benefits of electric water heating, automatic home laundries, and other electrical conveniences. Other groups, including vocational agriculture teachers, extension service representatives, and the colleges and universities, are concerned with improved farm living, increased farm production, and farm sanitation. Pump dealers are natural allies in this field.

These groups joined in a program to improve rural sanitation and to encourage more use of electrically powered pressure water systems on farms. The program was built around the ideas developed in Winston County, Miss., and in the Chestuee area of eastern Tennessee, namely, (a) cooperation among all interested agencies, (b) personal calls and home visits to farmers, (c) the questionnaire survey, and (d) group demonstrations. Two main activities were included:

1. A postcard survey of rural people was conducted, followed by personal calls at the farms of those persons who requested such visits from the health department and the rural power association.

2. A series of 1-day workshops on pressure water systems and sanitation was carried out. The workshops were a cooperative effort of the county health departments, the Mississippi State Board of Health, local power associations, the vocational agriculture department of the State department of education, the extension service, and TVA.

The Survey

County sanitarians and local power associations worked out a postcard questionnaire with these questions:

1. Is your water supply from a dug, bored, driven, or drilled well or from a spring or cistern?

2. Do you get water from its source by a pitcher, handforce, or electric pump or by rope and bucket?

3. Is your well protected by a concrete slab?

18 percent. As a matter of fact, there were 59 percent more individual protected water supplies installed in just one of the completely surveyed counties than in all of the 13 non-surveyed counties combined.

These figures indicate clearly that concentrated efforts on improved sanitation and increased use of pressure water systems will show definite results when the talents of several co-operating groups are focused on this problem.

The spread of this approach to other areas was inevitable. Already several power systems in Tennessee and Alabama are working with

local health officials and other groups on such a program. The Communicable Disease Center, Public Health Service, made a special request to have the water systems workshops program presented at two 1-day sessions near Atlanta, Ga. These workshops were enthusiastically received by those present.

More definite results will be available at a later date. Thus far, however, it seems certain that the program in northeastern Mississippi has done more to stir up interest in improved rural sanitation than any other approach to the problem.

1955 Water Supply Inventory

More than 52 million people in communities of 25,000 and over now depend on surface sources for their daily water supplies as compared with fewer than 40 million in 1948. The 1955 inventory of the Nation's water supplies also revealed that less than 1 percent of the

population in such communities use untreated water.

The inventory was compiled by the Public Health Service Robert A. Taft Sanitary Engineering Center, Cincinnati, Ohio, from data provided by State and local health departments.

¹ 1940 census. ² 1950 census.

to the top of this tower, the lecturer was able, in effect, to put the audience at the bottom of a well.

Subjects covered were:

- Water-supply protection and sewage disposal.
- Fundamentals of water systems.
- Selection of pneumatic tanks.
- Types of air volume controls and their correct use.
- Plastic pipe and its correct application.
- Pump location, housing, and protection.
- Selecting the pump with the necessary capacity and calculating suction lift and discharge head.
- Planning the farmstead distribution system.

Demonstrations presented were:

- Effects on pump operation of increasing suction lift and discharge pressure and of elevation of the pump.
- Airlogging and waterlogging of pneumatic tanks.
- The submersible pump.
- Pipe friction in various kinds of pipe.
- Wiring and motor protection.

In addition, each person at each workshop received a folder with some 20 pieces of literature on pumping equipment and pump installation.

Fifteen of these intensive 1-day workshops were held in Mississippi, with more than 350 leaders attending. One meeting was held at Mississippi State College, another at a Future Farmers of America camp, and the remainder at vocational agriculture departments of high schools.

Results

Perhaps the main benefit of this coordinated activity has been the establishment of effective day-to-day working relationships among the various participating agencies. While all of these agencies have a common interest—improvement of rural living—each individual agency has specialized fields of interest which contribute to achieving this goal of better rural life. It is the concentration of all these specialized talents on one particular aspect of rural life—the problem of sanitation and the general

benefits of pressure water systems—that seems to stand out as a major accomplishment.

It is too early to evaluate completely the effects of this activity on rural sanitation in northeastern Mississippi. This is obviously a long-range program, one which requires constant effort for a number of years. It requires followup calls and renewed activity each year. The program is not yet complete, and further results will be seen.

However, some facts are available, based on a study of 21 counties in northeastern Mississippi. This study, made from reports of sanitarians in these counties, shows the following results during the calendar year 1954.

1. Of all pressure water systems installed in the 21 counties in 1954, approximately 50 percent were installed in the 3 counties where the postcard survey was made on a countywide basis. Another 27 percent of the pressure water systems were installed in 5 other counties where the postcard survey was made in 10 to 25 percent of the county. In the remaining 13 counties, only 23 percent of the total pressure water systems were installed. Thus, more than three-fourths of the pressure water systems installed in these 21 counties in 1954 were in the 8 counties where the survey was made in all or part of the county; less than one-fourth of the pressure water systems were installed in the other 13 counties.

2. The statistics on installation of protected water supplies is even more impressive. In many cases, the sanitarian, who made a call to a farm after the postcard survey, found that improvements in the protection of farm water supply had already been made—in the interval between the farmer's mailing back the postcard and the visit of the sanitarian.

In the matter of protecting water supply, 55 percent of the improvements came in the 3 counties where complete countywide postcard surveys were made. Another 27 percent of improvements were in the 5 counties where surveys were made in part of the county. The remaining 13 counties produced only 18 percent of the improvements in protection of water supplies in 1954. Thus, the 8 counties where the survey was made in all or part of the county received 82 percent of the improvements in water supply protection, and the other 13 counties had only

¹ Per capita maintenance expenditure was computed by dividing total maintenance expenditure by the average daily resident patient population in each State.

² Estimated by using data reported in the 1954 census of mental patients for those hospitals not supplying the special survey data for 1955 and using the 1955 survey data for those hospitals which did report.

³ Estimated by using data reported for the 1954 census of mental patients since the hospitals in the State did not report in the special survey for 1955.

⁴ Estimated by applying, where required, the percentage change reported for similar data in the 1953 and 1954 census of mental patients to the 1954 figure since the hospitals in the State concerned did not supply the item requested.

NOTE: These data are provisional and subject to change. Public hospitals include the State and county hospitals for mental disease and the psychopathic hospitals.

Mental Patient Data for Fiscal Year 1955

ON THE BASIS of summary data submitted to the National Institute of Mental Health of the Public Health Service by the various State mental hospital systems for fiscal year 1955, figures in basic categories show a substantial increase over the year before.

Item	1954	1955	Percentage increase
First admissions..	121, 430	123, 771	1. 9
Readmissions.....	50, 252	55, 158	9. 8
Discharges.....	115, 796	118, 532	2. 4
Deaths in hospitals..	42, 652	44, 488	4. 3
Resident patients at end of year..	553, 979	560, 576	1. 2
Personnel employed full time at end of year..	138, 053	145, 032	5. 1
Maintenance expenditures:			
Total.....	\$569,490,492	\$622,603,423	9. 3
Average per capita.....	\$1, 038. 62	\$1, 119. 06	7. 7

Heretofore there has been a considerable time lag in publishing mental health statistics. Since data are needed on an up-to-date basis, public mental hospitals were asked on recommendation of mental hospital statisticians in their fifth annual conference, May 1955, to provide certain basic figures after the close of each

year: first admissions, readmissions, total discharges from the hospitals and deaths in the hospitals during the year; average daily resident population; resident patients and total personnel employed full time at the end of the year; and total maintenance expenditures for patients.

The National Institute of Mental Health made the survey in October 1955.

It was realized that final and complete data might not be available because of variation in reporting procedures and fiscal year-ending dates. Therefore, the hospitals were requested, if the answers to any or all of the items were unknown at the time of the survey, to enter their best estimates. However, some hospitals found it impossible either to report any estimate for a given item or to report at all. Since these data were to provide some measure of the extent of hospitalization in State and county hospitals for mental disease and the psychopathic hospitals, the institute attempted to provide rough estimates of the missing data. This was done in one of three ways:

1. If one or two requested items were not available and all other items were supplied, estimates of the missing 1955 data were made by extrapolation, using the 1953 and 1954 census figures.

2. If some hospitals within the State reported and some did not, the 1954 data from the census of mental patients were used for hospitals not reporting.

3. If no report was made for a State in the survey, the 1954 census data were used.

The table shows figures for each State and the type of estimation procedure used.

This special Public Health Service report was made by the Hospital Reports and Records Unit, Current Reports Section, Biometrics Branch, National Institute of Mental Health, Bethesda, Md. The unit is interested in comments on the report and its continuation.

Urinary Excretion of Fluoride Following Defluoridation of a Water Supply

By R. C. LIKINS, D.D.S., F. J. McCLURE, Ph.D.,
and A. C. STEERE, B.S.

PREVIOUS studies have shown that essentially all absorbed fluoride is eliminated in the urine or deposited in skeletal and dental tissues (1-3). That all fluoride deposited in the skeleton is not fixed irreversibly is shown by its mobilization following a reduction in fluoride intake (1, 3-9). Brun and his associates (4) reported that men who had absorbed fluoride from cryolite dust maintained a high level of fluoride in the urine for as long as 7 years following the period of exposure. Similarly, Largent and Heyroth (3) and Largent (5) found that urinary excretion of fluoride in excess of the intake continued at a progressively decreasing rate for as long as 2 years after the ingestion of large amounts of fluoride. Blake-more and his co-workers (6) observed that in cattle the fluoride content of the urine remained high for some time after they had foraged on pastures contaminated with industrial fluoride dust. Direct evidence of the withdrawal of

fluoride from bone has been obtained in cattle (6) and in rats (7-9).

It was not ascertained by these studies whether or not any factors in association with a reduction in fluoride intake influenced the mobilization of fluoride. It may be surmised, however, that variations in the metabolic activity of skeletal tissue due to age could alter the process. In support of this assumption there is extensive evidence that the degree of skeletal maturation affects the deposition and retention of ions other than fluoride normally present in calcified tissues (10).

The purpose of the present study was to investigate the relationship of age to the rate of mobilization of fluoride in a human population group exposed to an excessive amount (8 p.p.m.) of waterborne fluoride.

Organization of the Study

For more than 50 years before defluoridation was begun on March 10, 1952 (11), the communal water supply of Bartlett, Tex., contained 8 p.p.m. fluoride. Since this date the fluoride in the water has been maintained at approximately 1 p.p.m.

One hundred and sixteen white males who had used the Bartlett water supply for at least 2 years immediately prior to defluoridation and who were currently drinking Bartlett water composed the study population. Their numerical distribution according to age group, to-

The authors are with the Laboratory of Oral and Biological Chemistry, National Institute of Dental Research, Public Health Service. Dr. Likins is engaged in research pertaining to mineral metabolism and the chemistry of calcified tissue. Dr. McClure, who has been studying fluoride and dental caries for many years, is chief of the laboratory. Mrs. Steere, a biologist, is assisting in the laboratory's research projects.

World Health Day || "Destroy Disease Carrying Insects"

April 7, 1956

Many diseases cannot be spread without insect vectors. They are among the most ancient afflictions of mankind and have played their part in shaping his history. Malaria has influenced the rise and fall of civilizations. Epidemics of plague and of yellow fever have again and again decimated populations in the old and the new worlds, while outbreaks of louseborne typhus have often determined the outcome of military campaigns. Sleeping sickness and the less well-known disease onchocerciasis have held back progress on the African continent.

These and a score of other diseases carried by flying and crawling insects have enfeebled whole sections of the human race, depopulated fertile food-producing tracts, and held down man's levels of living particularly in the tropics but also in temperate climates. Despite the strides that have been made in our own day towards the control of many of these scourges, there is scarcely one which does not still represent an actual or potential danger to large numbers of human beings.

Most of these diseases have been known and feared for centuries, but it was only in the early years of the present century that painstaking research established with certainty the part of many different species of insects, such as mosquitoes, tsetse flies, sandflies, fleas, and lice, as well as of ticks, and mites, in transmitting a great number of pestilences.

In the first flush of enthusiasm following these discoveries it was thought that, once the carrier was known, any disease would be virtually conquered.

Indeed, in a relatively short time yellow fever was banished from most of the cities of the Americas. The incidence of malaria was reduced particularly in the towns and in the more temperate zones, and certain other diseases were successfully attacked.

Rapid progress, however, became possible

only after the discovery during World War II of the "residual" insecticides, of which the best known probably is DDT. The special character of these chemicals is that they remain deadly for periods ranging up to several months after application. One of their first triumphs was to strangle the threat of typhus epidemics during and after the war. Next, they proved amazingly effective when correctly used to control malaria, even in the sparsely settled rural districts. There is scarcely an insectborne disease against which these new chemicals are not being used today with greater or less effect.

But again disappointment has followed too optimistic hopes. First, the common housefly and now some mosquitoes as well as lice, cockroaches, and bedbugs in certain areas have shown that, after a few years of exposure, they can develop resistance which protects them from fatal effects. For the housefly, resistance occurs rather quickly, and these chemicals have therefore become of little value. With the mosquito, however, the insecticides can be used effectively for several years. During this period an all-out campaign can eradicate diseases such as malaria.

It would be a serious mistake to underestimate insectborne diseases. It is already clear that the residual insecticides, powerful weapons though they be, do not provide the final answer to the disease-carrying insect.

World Health Day this year will, I hope, serve to make people everywhere realize that, although the insectborne diseases are being increasingly held in check, they are not yet conquered. To achieve that final victory, man will need all his intelligence and resourcefulness. Above all, he will need to act in concert, for this group of diseases constitutes one of the greatest challenges to international health action.

—By M. G. CANDAT, M.D., *Director-General, World Health Organization* (abridged statement).

values agrees with previous reports that urinary excretion of fluoride continued to be high after a marked reduction in the fluoride intake. It also indicates that fluoride is being mobilized from the skeletal tissues of the Bartlett residents.

There was no apparent correlation of age with urinary excretion of fluoride within either the group 7 through 16 years of age or the group aged 20 years and over. When the mean fluoride values for these two groups are compared, however, it will be noted that during the first 20 weeks the urinary excretion of fluoride decreased somewhat less precipitously in children than in adults. This finding suggests that the degree of mobilization of skeletal fluoride was somewhat greater in children than in adults during this period.

It has been suggested that the withdrawal of fluoride from bone can be attributed to (a) exchange phenomena in which fluoride ions on the surface of the apatite crystals exchange with hydroxyl ions in the extracellular fluids and (b) to the basic resorption-deposition cycle of the skeleton (16). Since this latter process is identified with bone growth and reconstruc-

Fluoride content of water and urine at specified intervals after defluoridation of the water supply in Bartlett, Tex.

tion, it seems probable that exchange is the principal mechanism concerned in the mobilization of fluoride from the mature skeleton. On this basis the initial rapid decrease in the urinary concentration of fluoride in adults presum-

gether with data relative to duration of exposure to the untreated water, is shown in table 1.

On the day defluoridation was begun (which was, of course, before the defluoridation process had changed the fluoride content of the water supply) and at intervals thereafter during the next 113 weeks, a spot urine specimen was obtained from each person in the study. Aliquots of the specimens were pooled by age groups and analyzed for fluoride by standard procedures (12, 13), with calcium hydroxide (1 gm. per 100 ml. urine) employed as the fluoride fixative.

Results

The mean daily fluoride content of the treated water in Bartlett during the period of

observation was 1.32 p.p.m. The average fluoride content for each month is given in table 2.

The urinary fluoride values for each age group appear in table 3, and the means for all children, ages 7 through 16, and all adults, ages 20 and over, are shown in the chart. This division of the study population into children and adults was based on the fact that skeletal maturation is complete by approximately 18 years of age (14).

On the day defluoridation was begun, the fluoride content of the urine samples ranged from 5.0 to 9.2 p.p.m. and averaged 6.5 p.p.m. in children and 7.7 p.p.m. in adults. One week later, the water contained 0.7 p.p.m. fluoride, and the mean concentration of urinary fluoride had decreased to 4.9 p.p.m. in children and 5.1 p.p.m. in adults. After 5 weeks the mean urinary fluoride concentration remained unchanged in children but had decreased to 3.9 p.p.m. in adults. No further changes were apparent at the end of 9 weeks and 20 weeks, but the fluoride content of the urine had decreased in both children and adults after 39 weeks. After 113 weeks, the average concentration of fluoride in the urine was 2.2 p.p.m. in children and 2.5 p.p.m. in adults.

Discussion

It has been shown that persons whose drinking water contained 0.5 to 5.1 p.p.m. fluoride excreted fluoride in the urine approximately equal in concentration to that in the drinking water (15). On the basis of this evidence, the urine of the Bartlett residents would be expected to contain 1.0-1.5 p.p.m. of fluoride following defluoridation of their drinking water. The fact that the urinary concentrations of fluoride considerably exceeded these expected

Table 2. Average monthly concentrations of fluoride (p.p.m.) in the water supply of Bartlett, Tex., after defluoridation

Where are we going in public health?

THE CHRONIC DISEASES, mental disorders, medical rehabilitation, and the consequent need to evaluate and reevaluate all public health programs constitute, it seems to me, urgent challenges that confront our profession. We cannot do less than to face these challenges with resolution and daring. The courage to do what is necessary is as basic to the character of our organization as it is to the moral fabric of the individual spirit.

HERMAN E. HILLEBOE, M.D.

ably reflects the loss of readily exchangeable, surface-bound fluoride, whereas the somewhat less precipitous drop in children may be the consequence of the progressive liberation of fluoride from bone through resorptive activity.

Summary

The urinary excretion of fluoride was determined in children, ages 7-16 years, and in adults, ages 20 years and older, following the reduction of fluoride in their drinking water from 8 p.p.m. to approximately 1 p.p.m. During a period of 27 months, the concentration of fluoride in urine specimens decreased from 6-8 p.p.m. to approximately 2 p.p.m. The urinary fluoride values during the period were considerably higher than would be expected for a corresponding group with no prior exposure to high levels of fluoride. These values indicate that previously stored fluoride was being mobilized. There was no apparent relation between age and urinary fluoride excretion within either group. However, the extent of mobilization appeared to be greater in children than in adults.

Goals and Issues . . .

Fight Chronic Ills Now, APHA President Urges

APHA President Herman E. Hilleboe, M.D., New York State health commissioner, in his address of welcome, pinpointed challenging and complex public health problems which, he said, call for shrewd collective analysis and planning: chronic ill, mental health, rehabilitation, and evaluation.

Historic achievements in public health, minimizing the threat of communicable disease, Hilleboe said, have permitted more and more children to live to maturity. The result: public health work of the future must deal more and more with mature persons among whom chronic disease and disability are prevalent.

"Our public health programs must encompass the degenerative diseases and the long-term illness," Hilleboe said. "We cannot delay longer, or we will be hopelessly overwhelmed."

Chronic Diseases

The special problem in the prevention of chronic diseases is prevention of progression of the major causes of death, chiefly cancer, diseases of the heart, and cerebral vascular lesions, he said. Rehabilitation plays a predominant role in the prevention of other chronic ailments—arthritis, neuromuscular disorders, and diabetes, he added.

"As we apply new knowledge of cancer, we lengthen the life of affected individuals and increase the magnitude of the problems of chronic disease and especially rehabilitation," he pointed out. "The increase in life expectancy offers benefits to the individual, but at the same time it adds social and economic responsibilities for the community and State," he said.

Truly preventive geriatrics should begin during early adult life with sound health programs directed

against the chronic diseases as they begin to attack the aging body, he said, citing the pilot studies on atherosclerosis in Minnesota, the multiple screening studies in Virginia, the broad chronic disease program in California.

In Hilleboe's opinion, projects similar to the New York State research in cardiovascular disease, at the Albany Medical College, should be a vital part of all large health departments.

"What is the purpose of such a project?" he asked. "First of all, it gives a preventive service to State employees; but equally important, it is a research effort to learn how best to detect heart disease at an early stage and to develop new methods of effective and economical screening to find cardiac disease.

"We hope to gain basic knowledge of the preventive aspects of coronary artery disease and hypertension. We use this research project for the teaching of medical students and also for postgraduate education of general practitioners and health officers in the area. This is the type of project which should be a vital part of larger health departments, so that they may better meet the challenge of this crucial public health problem."

The theme "Where are we going in public health?" was a wise choice for the annual meeting of the American Public Health Association, Hilleboe remarked. The APHA Committee on Administrative Practice is sponsoring a study on what official and voluntary health agencies are doing on a communitywide basis to meet the problems of chronic illness, he noted. In 1956, the association plans to use its journal and newsletter, meetings of regional groups, State societies, and expert committees to bring the challenge of public health in a changing world to health workers everywhere, he added.

Mental Health

The establishment of a mental health section within the organizational structure of APHA is also an encouraging sign, he remarked, and made the following comments:

"It has been estimated that some 25 percent of the Nation's labor force suffers from some form of emotional disturbance. This situation and its attendant dislocations, in terms of wages paid for no productive results and in terms of damage to men and machines, cost industry billions of dollars a year.

"Every year a quarter of a million new patients enter mental institutions. Our mental health experts tell us that one out of every 12 persons will sometime during his life become a mental hospital patient, and that in the United States today there are some 10 million persons suffering mental illnesses or disorders. The personnel and facilities fall far short of the demands of these people who are swelling the ranks of the chronically ill."

In commenting that the public health movement has not done nearly enough to cope with the agonizing issues of mental disease, Hilleboe stated that public health and mental hygiene authorities in the States are complementary and never should be competitive. He urged close and continuing collaboration.

Other challenges to the public health profession Hilleboe discussed are the pressing demands for medical rehabilitation and the need to discover more precise tools with which to evaluate and reevaluate public health problems.

Rehabilitation

On rehabilitation, he had this to say:

"Public health physicians need to have an appreciation of the important part played by family doctors in this field. Public health workers can serve best by supplementing and enhancing the work of the family physician. Medical rehabilitation, viewed in this broad perspective, is a synthesis of the skills of the family

The APHA Conference Report

Highlights of more than 130 papers presented at the 83d annual meeting of the American Public Health Association and related organizations, at Kansas City, Mo., November 14-18, 1955, are published in the following pages. *Public Health Reports* here seeks for the fifth successive year to provide a compressed but comprehensive review of the Nation's major annual public health meeting.

It is intended that this information shall be helpful not only to the multitude who did not attend the conference but even to the few thousand guests and delegates at Kansas City who regrettably found it

impossible to attend more than one meeting at one time, not to mention luncheons, dinners, business meetings, discussions, and exhibitions.

Our editors have, with the assistance of the authors, selected and summarized the salient points of available papers for summation. The papers are arrayed below as nearly as possible according to the topical or professional interests they affect. To avoid repetition, we have refrained from identifying the sections or organizations which sponsored these papers, but a list of the sections and most of the organizations is published below.

The faith that knowledge of people is knowledge for people is for the psychologist a mundane practicality which coincides with the liberal democratic tradition.

The layman is already ahead of the professional in the quest for creative health. The profession is undertaking to apply behavioral knowledge for public use through such operations as the personnel and testing projects of the APHA testing office, the Behavioral Studies Section of the Public Health Service, and the Joint Council on Behavioral Science in Public Health.

Population Shifts Compel Review of Health Goals

Quantitative and qualitative changes in the United States population demand reappraisal of our ideas about basic health services and a basic health staff, declared John J. Hanlon, M.D., M.P.H., chief, Public Health Division, International Cooperation Administration.

Concerning the continued absolute and relative increase in the older population, Hanlon noted that in 1900, only 18 percent of our population was over 45 years of age, whereas today the figure is 30 percent. By 1975, an estimated one-half of our labor force will be over 40 years of age.

He stated that public health has been doing little more than "dabbling about in the vast area of adult health, chronic diseases, and geriatrics."

The recent upward trend in births indicates that all types of maternal and child health services not only must remain but must expand, Hanlon continued. The annual number of births is expected to reach 6 million by 1975.

Considering current personnel shortages and the prospective increase in population to 210 million or 230 million by 1975, Hanlon estimates that in 20 years we will need

about twice the number of public health workers now on the job.

"A considerable retooling job" by the professional schools is also called for, according to Hanlon. Goals, curriculums, and facilities should be subject to careful scrutiny and analysis, and extensive study should be made of the types of individuals who might be accepted for training, he said.

Spatial Changes

Spatial changes in the population, that is, more or less permanent changes in geographic distribution, have accentuated the gaps in medical and public health personnel and facilities, Hanlon specified. To improve the situation, he urged equitable sharing of support of professional schools and training centers and the development of satisfactory means of transferring accumulated job benefits, such as retirement and pension rights.

Among the several types of spatial change, Hanlon mentioned: the renewed movement of industries and businesses to the west, northwest, and southwest; the northward movement of the American Negroes; and the tendency toward "urban sprawl."

Indicative of population mobility, Hanlon said, is the fact that between April 1950 and April 1951, 21 percent of the population moved to another house. One-third of these families moved to another State or county.

Such changes are a challenge to environmental health, he pointed out. Urban and suburban slums must be avoided, new water and sewerage systems constructed, housing developments supervised, streams and the atmosphere protected against pollution, industrial hygiene and safety services extended to new plants, and entire communities educated in a new setting.

Temporal Changes

Applying the term "temporal change" to temporary population movement, Hanlon noted that temporal population changes give rise to somewhat specialized health prob-

lems—those of the traveler and the migrant worker, for example.

Much remains to be done to make both national and international travel hygienically safe in terms of contacts, food, drink, and waste disposal. "The sanitary needs of the traveler lag one or two generations behind improvements in speed and comfort, he said.

Increased worldwide travel may call for reemphasis of global epidemiology, Hanlon suggested. He believes also that more attention to quarantine activities, international standards, and carrier sanitation and examination will be required. "Coupled with this work, he said, is technical assistance in health to other countries.

Urges Stronger Emphasis On Industrial Health

Specific public needs in occupational health and in supervision of medical care were stated in behalf of organized labor by Leonard Woodcock, vice president, United Automobile Workers.

Speaking of labor's experience with occupational health services and with prepayment plans for medical care, he said:

"We urgently need a stepped-up program of industrial health. We need improved standards publicly arrived at. We need active and disinterested enforcement of standards. We need responsibly conducted public research on the key problems of industrial health to determine the extent to which cancer, heart disease, and other major disabilities are work connected. New studies are needed to keep abreast of the changing occupational environment which now exposes people to the risk of radiation and to the hazards of new chemicals and new materials. Improved reporting and detection programs are needed."

He said unions were getting better cooperation on health services from State labor departments than from health agencies. "Without excep-

physician and the public health worker each of whom contributes to the common goal of correcting or retarding the ill effects of disease and disability. This teamwork promotes optimum health for the community through preventive services to its individual citizens.

"Medical rehabilitation of the physically and mentally handicapped calls upon every field of activity in health, vocational service, and welfare. Not only must the many different needs of the disabled individual be met adequately, but the overlapping services require meticulous synchronization.

"Teamwork of the highest order is necessary from the beginning to the end of the rehabilitative process. Immediately after the medical members of the team diagnose disability and make a plan of treatment, the educational members join with their vocational guidance and training. The welfare team members also are concerned from the start with the social problems of the individual and the associated problems in the home in which the disabled lives.

"The same pattern of teamwork is needed among the several departments in State government concerned with medical rehabilitation. The rigidity of antiquated laws and the barriers of traditional practices too often stand in the way of realignment of duties and responsibilities to meet the present-day needs of the disabled. A new approach is essential. . . .

"For public health workers to direct and advise on the medical aspects of rehabilitation in no way interferes with the prerogatives of the guidance counselors, educators, and technicians in the vocational aspects of rehabilitation. Nor does it interfere with the employment experts in the departments of labor or education in the placement programs. Interdepartmental planning can solve these problems of relationship if the departmental representatives will only learn to communicate with one another, share burdens, and divide their responsibilities.

"Every State could benefit from an interdepartmental council in the field of human resources to make full use of available personnel and facilities in medical rehabilitation. Here is a productive interprise in which public health workers can take the initiative in those States that do not have such interdepartmental council.

"The future success of local health departments throughout the Nation may well depend upon the programs developed to serve citizens with chronic diseases, especially in the field of medical rehabilitation. Indeed, in planning to meet the future health needs of the Nation, let us not forget that a large share of adult medical care consists of medical rehabilitation."

Future success in meeting the challenge of chronic diseases, mental disorders, and medical rehabilitation depends on our collective ability to adapt to current demands and also upon the realism of our analysis and evaluation of the whole structure of public health activities, Hilleboe concluded.

Rule of Habeas Mentem Protects the Public

In the shape of things to come, public health services will be designed more and more by an informed and insistent public, according to Fillmore Sanford, executive secretary of the American Psychological Association.

Sanford discussed current social trends, their implications for public health, and anticipatory possibilities. This prospect of popular guidance of public health practice, he said, indicated an expanding responsibility for the behavioral sciences.

Increasing freedom from drudgery, increasing freedom from the major killing diseases, advancing levels of education, and increased scientific knowledge of the world, including knowledge of human behavior, he said, have their meaning for the

practitioners as well as the beneficiaries of health services.

The increasing knowledge of behavior, surpassing present understanding of the unconscious, the conditioned reflex, and intelligence, will permit people to improve their predictions of human behavior. As predictions improve, anticipatory action may be expected to improve, too, he commented.

In the public health profession itself, he said, there will be increasing attention to creative action, increasing pressure to change the character of the professions, and an expanding concern with behavior and mental health.

He observed that there are four distinct attitudes in health, productive of characteristic programs: the mood of passive acceptance, the curative attitude, the preventive policy, and the emerging concern with creative potentials, aiming ultimately to develop creative vitality in all living.

In the long trend toward creative health, he foresaw further democratization and secularization of health and welfare work. Informed and independent people, the products of improved education, will not take gracefully to the professional expert who assumes an autocratic role. They will resist prefabricated solutions served on a ritualistic platter, he said.

With such a public, the psychologist may serve best as a teacher and interpreter who can help individuals, in or out of the health profession, to straighten out their own behavior patterns. Such a psychologist observes the principles of habeas mentem, the right of a man to his own mind. Brotherly giving, rather than paternal direction, by the professional is rooted in the continuing advancement of knowledge.

Without progressive growth of knowledge, the professional feels pressure to keep secrets, to cultivate dependency, since such specialized knowledge is power. The best way to insure its use for the public good is to invest the power in the public.

POPULATION TRENDS

1. Home rule—government in the hands of the people back home, county health departments, decentralization of authority and responsibility.

2. Competence—professionally qualified officials without political motivation.

3. Legislation—to give local communities freedom to act; to place policy decisions in the hands of skilled administrators and professional decisions in the hands of professionals.

4. Problems of the aged—research on industrial retirement practices to determine what should be done about "young men of 65" and "old men of 50."

5. Preventive medicine.

6. Self help—home care programs and other treatments outside the hospital.

7. Mental hygiene.

In all these suggestions, the common theme is that people should be helped to help themselves, Moreell emphasized.

Legislation in 1951 which enabled Pennsylvania to establish county health units Moreell considered the State's most important advance in public health in recent years. "I believe that county health departments are the best mechanism for public health services in many areas," he declared. For example, they serve as effective means for providing service in the two important fields of off-the-job accidents and off-the-job sickness.

Population Trends Affect Public Health Planning

The volume of internal migration, the great increase in the child population, and the steady increase in the proportion of older persons in this country present actual and potential considerations in planning public health services, according to Robert D. Grove, Ph.D., assistant chief, National Office of Vital Statistics, Public Health Service.

The predominant direction of population migration to the far west and coastal areas, the rapid growth of urban and suburban areas, and the noticeable decline of the rural farm population are outstanding characteristics of population trends, Grove said.

A rapidly growing area is faced with the necessity of expanding its hospital, clinic, nursing, and sanitation services, he commented. It must succeed in obtaining large-scale financing, in convincing local governing bodies that programs of the necessary magnitude should be undertaken, and in getting new residents to share in decisions affecting the community's future. Sometimes, new residents bring with them certain health difficulties that were not previously significant in the community.

The movement to the suburbs usually removes many high income residents from the central cities and may reduce the personal and financial resources for maintaining health services for the city, he continued. This trend represents a hazard not only to the continued provision of health services to the residents of the city but also the health of the many suburban residents who work in the city.

The rural areas, many of which never have had adequate health facilities and services, may find it even more difficult to support them in the face of a declining population, he added. This decline may affect particularly the services for children.

There is reason to believe, he continued, that the number of women entering the childbearing period will begin to increase about 1960 and rise thereafter, and that by 1975 the number of children under 5 years of age will be about one-third more than at present.

One effect of the present tremendous increase in babies and children can be seen in the education field. By 1965, high school enrollment is expected to be about 50 percent higher than in 1955. The wave of additional children has affected needs for school health services, for prenatal care facilities and well-baby clinics, and calls for greatly expanded mental health facilities and larger programs for the prevention of serious accidents.

The number of persons 65 and older can be expected to rise by one-half between 1955 and 1975, he said. Although the attention of health and welfare agencies already is focused on the medical needs of older people, the future will see even greater ne-

GROWING & AGING POPULATION

tion," he said, "State health departments do not have the staff needed to enforce statutory standards of occupational health and safety." He added that essential information is irrevocably lost because of inadequate reporting of occupational disease.

Speaking of labor contributions to the growth of prepayment plans for health services, he said, "Under health programs negotiated by our union alone, over 3 million workers and dependents have hospitalization and medical coverage. The annual cost of these coverages is about \$130 million. Usually the cost is split between the employer and the worker. The employer's share, however, is part of the worker's compensation; it is an item over which his union conducts collective bargaining and it is paid in lieu of increased wages."

He voiced several familiar criticisms of the operation of prepayment plans, with emphasis on the fact that the subscribers have little capacity to assess the quality of the services and that the plans give far too little attention to preventive services which might enable subscribers to secure effective health services at reasonable costs. He felt that a stronger government interest in the operation of prepayment plans was warranted in view of the fact that subscribers constitute a majority of the population.

Although labor has always favored a system of national health insurance, as the most effective way to obtain comprehensive health services, he said there was no choice but to give the voluntary system a fair trial. However, he added, public health agencies have "an inescapable responsibility concerning the quality of care." And he said they are derelict in developing comprehensive preventive health services.

"Public health should conduct programs of research on how to organize and administer medical care and extend its scope to prevent illness, furnish rehabilitation, and guarantee that institutions and persons licensed to practice do indeed give high quality care," he said.

The issue between national health insurance and the voluntary prepayment plans, he concluded, will be determined in the long run by the availability of broad, voluntary prepaid programs whose scope and quality is assured. "The challenge to public health," he asserted, "is to move into this field as a representative not of the healing arts profession, but on behalf of its citizens."

An Industrialist Looks At Public Health

Most industrial companies now recognize their obligation to be good neighbors and that "their greatest asset is the health of their employees. They see a direct relationship between efficiency and health, which includes the health of the worker himself and that of the people in his home and in his community," stated Admiral Ben Moreell, chairman of the board, Jones and Laughlin Steel Corporation, Pittsburgh, Pa.

"If we would reap the full benefits of our American traditions, each of us has a moral obligation to contribute, voluntarily and generously, to the preservation of the health of the individuals who make up our society," he said.

Speaking as an industrialist, he said he would list our current major health problems under six headings: (a) the aging population, (b) chronic diseases, (c) mental hygiene, (d) industrial health, (e) hospital and medical care, and (f) prevention of accidents.

"As we assume responsibilities in these areas, we must have the courage to eliminate current programs which deal with obsolete problems," Moreell declared.

He decried the huge expenditures "for 'warehousing' the sick, the tired, the helpless aged, and the indigent," which are "in painful contrast to the meager sums spent for prevention of these disabilities." In Pennsylvania, for example, nearly \$10 million is spent annually for

tuberculosis hospitals. This sum, he said, is sufficient to finance a vigorous preventive campaign that might well end the scourge.

Industrial Medicine Opportunities

Many industrial health programs too, according to Moreell, are still in the "horse and buggy stage." But there is growing realization that our Nation's 65 million gainfully employed provide an excellent opportunity for the furtherance of effective preventive medicine, he said.

"We regard our industrial health program as one of preventive medicine which cooperates with constructive public health activities," he declared. The goal is conservation, protection, and furtherance of health and capabilities of the individual worker.

Viewing occupational health as an ally of public health, he stressed the need for greatly expanded cooperation between the two. He mentioned, for example, that inplant medical activities afford important opportunities for mass studies of certain diseases.

"We should proceed with a bold attack on this front in the hope that from mass studies we will obtain knowledge that case-by-case studies have not provided," he asserted.

Another area in which the lessons learned in industry can be applied outside the plant is that of the so-called fringe benefits. "If we could obtain accurate statistical data," he said, "we could avoid many disagreements on objectives and methods and provide greatly improved service to our employees with little increase in cost."

Also needed is research which will tell us how to reduce the cost of medical care without reducing its effectiveness. We have reached the point, he remarked, where we must take definitive action to teach folks how to care for sick people at home, especially in chronic illnesses.

A Campaign Platform

Moreell suggested the following platform for a campaign to improve public health practices:

Leroy E. Burney, M.D., Assistant Surgeon General, deputy chief of the Bureau of State Services, Public Health Service, said that while recruitment must be stepped up the energies of the professional public health worker must also be redirected in order to gain the fullest use of his service.

He suggested that the professional worker should rely to a much greater extent on the talents of the nontechnical members of the public health team.

"We have hardly begun to appreciate the major contributions that homemakers, nurse aides, practical nurses, business administrators, executive assistants, and sanitarians can make to public health," he said. "By delegating many of the daily operations not directly related to his professional skills, the highly trained worker will be able to devote a much larger part of his valuable time to problems requiring his special competence. Only in this way will the professional worker be able to meet the ever-increasing demands for his services."

Trainee Selection

William C. Cottle, Ph.D., professor of education and assistant director of the guidance bureau, University of Kansas, believes that research into the traits of successful persons in public health occupations will yield material which can be utilized in schools and recruitment and improve staff productivity.

Efforts to date have been concentrated on telling people about, and selling them on, the advantages of careers in public health. Now we need to discover the kind of people who are and are not successful in the varied fields and the traits that make them successful, he said.

Cottle advocated the same scientific research approach to the selection of trainees in public health that are used in identifying, treating, or preventing an infectious disease or in solving any other major scientific problem.

"Before we can award scholarships and fellowships, we need to

know what kind of scholars and fellows we want," he explained. "The range of jobs in public health covers people with varied traits, and a person unsuited for one occupation in public health may have the aptitudes, abilities, and interests that fit him for success in another field of public health."

Cottle also suggested part-time employment of public health workers who become housewives.

Perry Sandell, M.P.H., director of the bureau of dental health education, American Dental Association, stated that future health manpower needs can be more definitely determined after we have been able to make the most effective use of health personnel now available.

"We hear repeatedly of the misuse and waste of the special skills of people engaged in public health work. Not only does this result in ineffective use of personnel, but often results in loss of health personnel because of job dissatisfaction," he said.

On the Job Training

Ross Kandle, M.D., deputy commissioner of health of New York

City, advised that an active accredited residency in preventive medicine is essential in recruiting physicians. The New York State Department of Health, he said, has six young physicians in training for careers in public health.

Kandle also advocated advanced training and education on the job. Well-grounded sanitarians might go to night school in urban areas and with help from a health department become engineers, he pointed out. Nurses recruited at staff level can be helped to get basic training in public health if they and the agencies both believe that adequate training in public health nursing is worth while.

An attractive pension plan is vital in holding a staff, he said, and important in getting people who will have an opportunity to grow on the job.

Also discussed at the session was the Health Career Horizons project of the National Health Council, which is putting information on all health careers within the reach of the Nation's high school students and their parents, teachers, and counselors.

World Health . . .

Eradication of Malaria, A World Health Goal

Ever since the Interim Commission of the World Health Organization inherited certain malaria control programs from UNRRA in 1946, WHO has placed top priority on helping governments to initiate or expand malaria control programs in all countries in which the disease is a serious problem, declared Louis L. Williams, Jr., M.D., consultant to the Pan American Sanitary Bureau, WHO Regional Office for the Americas.

By the end of 1954, a dozen coun-

tries or territories had eradicated or almost eradicated malaria, and the various agencies assisting malaria control—WHO, UNICEF, and the USICA—now are recommending the abandonment by all countries concerned of the restricted idea of control in favor of intensified campaigns aimed at achieving complete eradication as soon as possible.

Growth of the Idea of Eradication

To illustrate how the concept of eradication has developed, Williams reviewed briefly malaria control activities in the United States from the early years of this century to the

cessity for additional services in this area.

It is necessary to recognize the major trends, but it is important for analytical or administrative purposes to investigate also the variations within the trends. Grove concluded. Among the variations he discussed were the rates of urban (white and nonwhite) population change, the loss in population of many areas, the variation between areas in the rate of child population increase, and the reverse of the decline of medium-sized families.

Negro Gains Status In Medical Services

Racial integration of medical or health services has progressed notably in the past 20 years, according to limited data obtained by Paul B. Cornely, M.D., Dr.P.H., head of the department of preventive medicine and public health, Howard University College of Medicine, Washington, D. C. It touched a low ebb early in the 1930's, gathered steam in the 1940's, and in the last few years has found general acceptance, at least on a token basis.

In 1936, of 73 Negro graduates of medical schools in the United States, all but 8 received their degrees from Howard or Meharry. For those who were graduates of medical, dental, nursing, and pharmaceutical schools, opportunities to practice were limited. Membership in professional societies was restricted if not closed. Of 7 States surveyed in 1930, 1 employed 2 Negro physicians on a part-time basis and 3 employed 29 Negro nurses.

The quality and number of hospital beds available to Negroes in the southern States was such that, to meet the need, 183 so-called Negro hospitals had been established. Of this number, 20 were approved for intern training. Philanthropic aid for Negro health came almost exclusively from Julius Rosenwald and the Rockefeller Foundation. Voluntary health insurance, which had its

origins in the 1930's, in no way touched the Negro population.

One of many developments toward the end of the decade was the realization that health clinics with Negro patients would enhance results by employing competent Negro professionals, Cornely noted. This reflected, he said, a changing social attitude, accelerated by surveys of needs and costs of medical care and by the emphasis on racial issues in international affairs.

Medical Doors Opening

In 1946, the American Nurses Association established a direct national membership for nurses who were not admitted to membership in their county societies. The Baltimore County Medical Society in Maryland opened its doors to Negro doctors in 1948. Oklahoma and Missouri followed suit in 1949. The University of Arkansas in 1948 became the first of 26 southern medical schools to admit a Negro student. The number of Negro students enrolled in medical schools in the north increased to 118. Internships and residencies opened in about 16 more institutions in 1948. The Hospital and Construction Act in 1947 included an antidiscrimination clause.

Although the proportion of Negro students in medical schools in 1955 was still small, it was up to 2.5 percent in Michigan. The average was less than 1 percent in the other northern schools. The northern average was about the same as in the southern medical schools, other than Howard and Meharry. Nevertheless, 8 of the once restricted southern medical schools in 1955 had a total of 43 Negro medical students.

All southern State medical societies, with the exception of Louisiana and possibly North Carolina, have opened their rolls to Negro physicians, even though as yet only a minority have taken up membership. Negro nurses and pharmacists are able to join their national professional societies without going through local or county units. The Negro dentist in the south, however,

is still barred from membership in the American Dental Association.

Patient Care

Negro enrollment in health insurance plans is difficult to measure because membership is not recorded according to race. Estimates of membership in various plans range from 1 to 20 percent. All insurance plans, with the exception of two in the south, report that Negro physicians participate, if available, in surgical plans.

Cornely's figures indicate that four-fifths of the general hospitals in the north now offer patient care without racial distinction, but such integration applies in only 4 of 69 general hospitals in the south. A similar differential is found between special hospitals of the north and south. About 10 percent of the northern hospitals offer residencies to Negro physicians and 20 percent permit membership on the active staff. Staff privileges are somewhat more available in southern hospitals, where Negro physicians are expected to serve patients in segregated wards.

Services provided by health departments in the north are predominantly but not wholly integrated. Of 23 cities, 13 reported employment of Negro professionals in official health agencies. Of 8 southern cities, only 2 reported integrated services, and all employed Negro professionals.

Among 200 voluntary health organizations in the north, 1 out of 6 employ Negro professionals, and a similar proportion—but not the same organizations—have Negro board members. The proportion was somewhat higher in the south.

Health Manpower Angles Explored by Panel

"Where do we get our manpower?" This basic question in providing adequate health services for America's millions produced a variety of answers from a public health panel.

Leroy E. Burney, M.D., Assistant Surgeon General, deputy chief of the Bureau of State Services, Public Health Service, said that while recruitment must be stepped up the energies of the professional public health worker must also be redirected in order to gain the fullest use of his service.

He suggested that the professional worker should rely to a much greater extent on the talents of the nontechnical members of the public health team.

"We have hardly begun to appreciate the major contributions that homemakers, nurse aides, practical nurses, business administrators, executive assistants, and sanitarians can make to public health," he said. "By delegating many of the daily operations not directly related to his professional skills, the highly trained worker will be able to devote a much larger part of his valuable time to problems requiring his special competence. Only in this way will the professional worker be able to meet the ever-increasing demands for his services."

Trainee Selection

William C. Cottle, Ph.D., professor of education and assistant director of the guidance bureau, University of Kansas, believes that research into the traits of successful persons in public health occupations will yield material which can be utilized in schools and recruitment and improve staff productivity.

Efforts to date have been concentrated on telling people about, and selling them on, the advantages of careers in public health. Now we need to discover the kind of people who are and are not successful in the varied fields and the traits that make them successful, he said.

tries or territories had eradicated or almost eradicated malaria, and the various agencies assisting malaria control—WHO, UNICEF, and the USICA—now are recommending the abandonment by all countries concerned of the restricted idea of control in favor of intensified campaigns aimed at achieving complete eradication as soon as possible.

Growth of the Idea of Eradication

To illustrate how the concept of eradication has developed, Williams reviewed briefly malaria control activities in the United States from the early years of this century to the

eradication campaign of the late 1940s

Among control highlights were the extension to rural areas of methods of killing mosquito larvae through use of oil and wind blown paris green, the development of county-wide malaria programs accompanying the growth of rural county health departments, and drainage involving the digging of more than 60,000 miles of ditches, which Williams stated 'went a long way toward breaking the back of the malaria problem'. Intensified malaria control programs during World War II carried out by State and county health departments in cooperation with the Public Health Service, and aimed particularly at protecting Army training camps in the south, brought further progress in removing malaria as a health menace.

As a result, the concept and feasibility of eradication of malaria from the United States came to be accepted and in 1945 the Public Health Service requested an appropriation to help health departments continue and extend the wartime programs, and to include all areas in which malaria still existed. In 1945 this was termed the *Extended Malaria Control Program*, but in 1947 the funds were being appropriated unequivocally for malaria eradication as such.

DDT and Chemotherapy

In 1946 DDT became available for malaria eradication in the United States and was also used overseas by the military. DDT as a residual spray is effective at low cost. It has led to eradication, but it has also led to a need to achieve eradication before resistance to DDT develops in the anopheline mosquitoes.

Williams called attention to another sting to the malarialogists bow—chemotherapy. Antimalarial drugs such as chloroquin, primaquin and pyrimethamine attack the malaria plasmodium within the human body and prevent its development and transmission.

Global Eradication

As programs become nationwide, he said, there is a need for their expansion into regional programs, a function of international agencies. In 1950 the Pan American Sanitary Bureau resolved upon a continental eradication program, and in 1954 the 11th Pan American Sanitary Conference decided to hasten this process by resolving that member governments should convert all control programs into eradication campaigns within the shortest possible time.

In 1955 the Eighth World Health Assembly requested governments throughout the world to intensify malaria control plans so that eradication may be achieved, and it authorized increased WHO assistance to governments. UNICEF appears willing to multiply by 4 or 5 times supplies to antimalarial activities where the goal is eradication.

At the end of 1954, the situation in five of WHO's regions was encouraging. In Africa great distances and depressed economies make eradication seem a utopian goal, although this need not be so if administrative obstacles are overcome. Williams outlined WHO functions, which include technical assistance and training in malaria control as a part of building strong national health departments, and which are supported by the knowledge of a worldwide panel of experts. Much of WHO's malaria activities are financed by United Nations technical assistance funds, and UNICEF provides large amounts of insecticides and equipment.

Throughout the world (excluding the Iron Curtain countries and most of Africa) some \$32 million is being expended this year in fighting malaria. WHO estimates that approximately doubling this amount could convert all control programs into eradication campaigns. As the campaign approaches its end, Williams concluded it is inevitable that more assistance will flow from the more fortunate nations to countries with low economic resources to enable

them to eradicate malaria and remove the hazard of reinfection. "When that time comes, the World Health Organization should have no difficulty in achieving the ideal objective of global malarial eradication," he said.

UNICEF Gives Top Priority To Malaria Eradication

For the immediate future, the United Nations Children's Fund (UNICEF), like the World Health Organization, will give priority to malaria eradication, announced August R. Lindt, LL.D., minister plenipotentiary, permanent observer of Switzerland to the United Nations and member of the Executive Board, United Nations Children's Fund.

UNICEF's Executive Board, he stated, has endorsed increases in aid to governments wishing to intensify drives against malaria. At its September (1955) session, it approved assistance for eradication campaigns in El Salvador and Mexico. The allocation to Mexico—\$2,400,000 for the first 18 months of the government's 5 year campaign—is the largest single sum ever voted by the Fund. UNICEF aided malaria eradication campaigns are under way also in Haiti and in Trinidad and Tobago.

Trachoma and leprosy, both of which take a high toll of child health, are other diseases which promise to assume greater importance among UNICEF aided programs, Lindt said. WHO and UNICEF assisted efforts to combat these diseases, he pointed out, had to await the development of techniques which make possible relatively low cost and far reaching campaigns.

Explaining the role of UNICEF in world health activities, Lindt noted that its exclusive function is to provide aid for improving the welfare of children as the name implies, and that its aid is primarily in the form of supplies. Except in emergencies,

assisted countries match the dollar value of UNICEF aid. Over the years, he said, their average expenditure has been \$3 for every \$2 from UNICEF.

In all its work, Lindt stated, UNICEF relies on the Food and Agricultural Organization and the World Health Organization, which provide aid primarily in the form of technical assistance, for assurance that its policies and planning are based on sound technical ground. He called special attention to the WHO's division of maternal and child health, which works closely with UNICEF.

Current Programs

This year UNICEF-aided disease control and nutrition campaigns are benefiting more than 32 million children and expectant and nursing mothers, Lindt reported. He mentioned the following specific UNICEF contributions: BCG vaccine, which is enabling WHO/UNICEF programs to vaccinate 14½ million children against tuberculosis; DDT, which is protecting other millions against malaria; penicillin, the sulfones, and other drugs, for use against yaws, leprosy, trachoma, and other diseases; and milk, which is the foundation for a multitude of child nutrition programs. Powdered milk, he noted, is donated to the Fund from United States' surplus supplies; the Fund pays only the cost of transportation.

Maternal and child health centers set up or improved with WHO/UNICEF aid number 5,000, he said. As an example of the results of this work, he gave the following data for West Bengal, India: In December 1953, when first shipments of UNICEF equipment for health centers were due, 6,700 children and mothers made first visits to maternal and child health centers in the area. In March 1955, 58,000 made first visits.

Help in developing facilities for improving local dairy industries and for the manufacture of other protein-rich, low-cost foods is another UNICEF activity, which is being conducted in cooperation with FAO,

according to Lindt. As examples of the latter, he mentioned a plant in Indonesia which will process a drink made of soybeans, peanuts, and malt and a fish flour production plant in Chile.

NTA Director Considers World Control of TB

The elimination of all human infections caused by tubercle bacillus, the goal of tuberculosis control in the United States, can also be the world goal in tuberculosis control, maintained James E. Perkins, M.D., managing director, National Tuberculosis Association.

"I know of no valid reason why this goal may not be capable of fulfillment if one does not attempt to put a time limit of its achievement," he said.

Even in countries with an astonishingly high tuberculosis rate, areas of comparatively little or no infection can be found, he noted. Is it too much to hope that such areas can be enlarged gradually until finally the spots of high prevalence fade and disappear?

Particularly encouraging in accomplishing such a feat, Perkins felt, is the indication that, with new drugs, the expensive and slow step of hospitalization can be minimized. He emphasized, however, that he was not suggesting that hospitals are no longer necessary, and he pointed out that carefully controlled, extensive trials of drugs in outpatient treatment of tuberculosis are barely begun.

Perkins also is hopeful for the development of a completely acceptable vaccine suitable for universal application. This would be even more of a shortcut to the eventual eradication of tuberculosis, he said.

He is aware, he remarked, that some experienced epidemiologists consider such a goal unrealistic. They point to the fact that the tubercle bacillus is only one of many causes of tuberculous disease and therefore object to calling it the primary cause.

"But in the absence of the tubercle bacillus," Perkins pointed out, "there can be no tuberculosis regardless of the degree of malnutrition, mental trauma, poverty, overcrowding, war, or the multitude of other overlapping and ill-defined factors frequently associated with the development of tuberculous disease; furthermore, there seems little doubt that an individual will develop tuberculous disease if he receives a sufficiently heavy infection of tubercle bacillus regardless of his resistance. It therefore seems quite proper to refer to the bacillus as the primary cause and the other factors as secondary causes."

Perkins doubted that cyclic reductions and resurgence of tuberculosis are inevitable in the future, in view of the specific control measures now available.

International Activities

According to Perkins' brief review of international activities, definite progress is being made in reducing the tuberculosis problem, but the progress is admittedly slow. WHO and UNICEF, he said, have almost necessarily limited their tuberculosis work largely to mass administration of BCG.

Dr. Chandra Mani, director of the WHO Regional Office for Southeast Asia, recently was reported to have said that the fight against tuberculosis, though intensified, is not even approaching the threshold of success in his area, Perkins stated. Dr. Mani stressed that, lacking any swifter and more potent weapon than the BCG vaccine, tuberculosis "will remain public health enemy No. 1 for some years to come," Perkins noted.

But WHO is exploring other solutions, Perkins said. More or less summing up the international situation in tuberculosis control are the following statements which he quoted from a *WHO Chronicle* review of the Director-General's annual report for 1954:

"... in countries where within 5 years the [tuberculosis] mortality has diminished by about half, the

number of reported cases of tuberculosis has dropped little, and the number of known infectious cases has sometimes even increased."

"... mortality figures can no longer be used as an index of the incidence of the disease . . . the prolongation of life in patients seriously afflicted with the infection may result in greater need for public health measures for their rehabilitation and assistance; and the epidemiological significance of widespread chemotherapy will have to be determined."

The review went on to say that "problems such as these are being given serious consideration by WHO. It is urgent, for example, to determine how effective ambulatory chemotherapy may be in areas where institutional facilities are not, and cannot be, adequate to meet the need for isolation and treatment."

Improvement in Sanitation Faces Slow Going

From a global standpoint, no great change in sanitation practices may be expected in less than a generation, because they must depend primarily on the children and youth of today, stated Herman G. Baity, Sc.D., director of the division of environmental sanitation, World Health Organization.

Sanitary management of shelter, water resources, food service, wastes, and vectors is slow to improve, particularly in areas where its significance must be learned, habits changed, and facilities built and used, he pointed out. Within the next 5 years, however, he believes that all governments can accomplish the following basic things:

1. Recognize the real benefits of sanitation to the health and well-being of their people.
2. Establish a sanitation unit within the national health service and staff it with personnel competent to plan and direct all phases of work in this field.
3. Integrate sanitation with other public health undertakings.

4. Develop a long-range plan of sanitation for the country as a whole, into which projects and programs may be fitted logically as to time and place.

5. Realize that it is possible to do something helpful in environmental sanitation under any conditions and under any budget and that the simplest things are often the most important.

6. Select a point of beginning, always the most difficult step, and outline an orderly progression of work and objectives.

An Urgent Necessity

Pointing out that an examination of the reasons for inaction and unsuccessful projects in sanitation is not only an instructive exercise but an urgent necessity if future planning is to be soundly based, Baity gave considerable attention to these aspects of international health work.

One reason for the slow development of sanitation programs in some areas, he said, is a lack of real understanding of the meaning and potential of sanitation. For example, the term is used sometimes to refer only to excreta disposal, he remarked.

In other areas, a sense of despair engendered by the sheer enormity of the task prevents action being started, he noted. Such an attitude, he said, is often heightened by fear of unknown and possibly high costs of necessary construction, and little or no effort is made to analyze the relative costs to local governments and to individuals.

Still another deterrent sometimes encountered is the expectation that, if action is delayed at local levels, sooner or later a higher level of government will accept responsibility and, in some magical way, do the work without cost to the community.

Reasons for unsuccessful projects, according to Baity, include these: no plan into which the project fitted logically as to time and place; lack of real integration of sanitation into the general health services of the country; inadequate attention to the education of the people expected to use the improved facilities or fail-

ure to enlist their active participation in construction and maintenance; lack of sufficient qualified personnel to carry out the various functions; absence of a fiscal plan for the upkeep of the project and its extension into a broader program.

Positive Results

On the positive side, Baity noted that, under the stimulation and guidance of WHO and other international agencies, the member countries of WHO are showing a noticeable upsurge of interest in the improvement of sanitation, particularly in Southeast Asia and Latin America. He mentioned, for example, the sanitation programs in Ceylon, India, and Burma. He also mentioned that the Pan American Sanitary Bureau has recently been asked to supply engineers for sanitation work in Nicaragua, Venezuela, Colombia, Mexico, and Uruguay.

WHO, an association of states organized for cooperative effort, provides "an unparalleled opportunity for bringing knowledge, skill, experience, and means . . . to bear upon the forces of ignorance, apathy, poverty, and despair which have so long imposed a cruel burden," Baity concluded.

WHO-Member Countries Relationship Defined

A pattern of give and take for the common good based on mutual respect, close and frequent contact, and cooperative effort characterizes the relationship between the World Health Organization and its 80 member nations, stated Henry van Zile Hyde, M.D., chief of the Division of International Health, Public Health Service, and United States member of the World Health Organization's Executive Board.

Through WHO, "the spirit and machinery of effective permanent relations between nations have been created in the field of health, and they are operating smoothly and well," he declared.

Twice a year, Hyde pointed out, the health authorities of the world set aside their own business and travel great distances to meet together to consider one another's problems. He was referring to the annual world health assemblies and the annual meetings of the WHO regional committees. The latter, he said, provide an opportunity for governments to talk with their neighbors about health problems of their neighborhood.

The technical personnel of the WHO staff are another contribution of the member countries. The member countries have been most generous in making available for WHO work many of their top public health leaders, even though they leave a vacuum in their own country's health work, Hyde said. The WHO staff, now numbering 1,307, is larger than that of any other agency within the framework of the United Nations except that of the United Nations itself.

The Receiving Side

Discussing the receiving side of the relationship, Hyde noted that in the beginning member nations did not know what to expect or what to seek in the way of help from WHO. Some wanted supplies; others wanted money; and still others wanted technical advice and assistance. The last is what WHO had to offer, he said, and the product proved so good and was presented in such a spirit that all the nations rapidly recognized its value. A parade of requests which taxes not only the finances of WHO but also the intellectual capital available to it is the situation today.

There is no stigma attached to requesting aid from WHO, Hyde emphasized, and he pointed out that competent leadership requires a recognition of one's own limitations and the ability to find ways to compensate for them. The progressive and dynamic leaders of public health are therefore the very ones who have asked most frequently and fervently for help, he said.

Greatly strengthening the relationship between WHO and its mem-

ber countries, according to Hyde, has been the creation of regional offices covering several countries or the stationing of representatives in individual countries. Through these devices, WHO is in intimate daily contact with the ministers and directors of health, as well as with the entire health staff, of each country, he noted.

Hyde calls the trust and friendship developed among the health leaders of the world through WHO during its short history phenomenal. They carry over into the operating relations between WHO and the governments, he said, so that when WHO deals with governments, professional friends are dealing with professional friends.

Education Is Vital Factor To Health in Asia

The high priority of health education is well recognized in many areas of the world which heretofore have been isolated from scientific progress, according to Jennelle Moorhead, M.S., a recent traveler to many Asian lands. Mrs. Moorhead is associate professor, general extension division, Oregon State System of Higher Education, Eugene, Oreg.

Successful introduction of sanitation procedures in the Far East and Middle East, Moorhead said, hinges on helping Asiatic people gain an understanding of the relationship of disease to water contaminated by indiscriminate disposal of human excreta.

"The preservation and acceptance of what we in the United States consider fundamental environmental sanitation concepts is not a simple matter in Asiatic countries," she said. "The educational problem for them is complicated almost beyond our understanding. The health concepts we have accepted and which should be taught may violate or challenge religious, cultural, or philosophical views. No matter how advantageous environmental sanitation and health education facts may

appear to those of us in Western civilization, if they are to be accepted . . . they will have to be related to the values and attitudes underlying the practices of each locality in each country. New ideas must be linked to traditional beliefs. They must not violate religious beliefs or folkways which vary from country to country and from village to village within countries."

Adult health education and school health education will need to proceed simultaneously to avoid alienating a child from his family and its cultural pattern, she believes. School health education has first to overcome the burden of illiteracy.

"I returned from my study trip with deep respect and admiration for the Asians who are attempting to solve their health and education problems and with an intense feeling of pride in the American educators and public health officials who are giving technical advice and assistance," Moorhead said.

The strong PTA movement in Japan and Turkey and the village development program in India and Pakistan are the most notable developments in the seven countries visited, she said in reporting the following.

Japan

Japan's health and education programs show a strong degree of westernization. Health instruction is taught in secondary schools by teachers whose preparation included training in health education. School health services are provided by nurses and physicians employed by the public schools. City elementary schools have health rooms with dental chairs.

The health of Japanese children will be greatly influenced by their aggressive parent-teacher organization, whose membership of 13 million has been instrumental in teaching democratic procedures. This movement and similar organizations have been helped to function successfully by the Division of Social Education, which is part of village, city, and prefectural government structure.

Thailand

Thailand's greatest needs are in environmental health, malaria control, medical care, medical education, and organization of health departments. Despite production of abundant food there is malnutrition. The use of eggs, chicken, fish, and unpolished rice in the diet must be encouraged. Food is served with no awareness of the germ theory of disease.

A division of school health and a division of health education in the Ministry of Public Health are developing a long range health education program. The emphasis will be on production of a basic curriculum for teacher training, carefully related to Thai culture and community health problems. School sanitation surveys are to be scheduled. Thai schools must be open enough to allow free circulation of air, closed enough to keep out rain, and set high enough to allow water to flow under. Rural schools do not have a safe water supply or even the old-fashioned privy.

India

Cementing all programs for the improvement of living in India and Pakistan is the village development program which involves 85 percent of the population. The village worker is the key person, trained to work with the village leaders. An allied development is the program of social education and instruction in village handicrafts so that young farmers are taught handicrafts that will produce income for their village.

Training is planned so that workers and the villagers advance in knowledge together. Both receive some rudimentary training in sanitation and some information on better agricultural methods. The village worker is oriented in basic techniques of village work as well.

The present major health focus is on environmental sanitation. One hundred programs encompassing 30,000 villagers are under way to construct 90,000 safe wells. Everyone who works on this program will be a potential health educator.

Cultural attitudes and costs complicate the building of toilet facilities. An oriental squat plate with a water seal that can be supplied at low cost by the government seems to be the answer for a latrine that meets sanitary and folkway requirements. The pride of ownership should increase its use.

Pakistan

A visit to refugee camps in Pakistan and India helps one realize the magnitude of the problems created by partition of the countries in 1947.

Only 379 nurses were left when partition necessitated the departure of the non Moslem nurses. Some 300 nurses have since been trained, but there is still only 1 nurse to 100,000 population.

Today there is a nursing council to promote the training of nurses. Two hundred health visitors have been trained in the four centers established for training in maternity and infant care.

In Karachi, where the first school physician in Pakistan was appointed in 1951, school health work will start in the secondary schools, where the enrollment is 25,000. Of 2,000 examined, 40 percent were healthy. Vision defects are frequent, however. Presently there is a vigorous campaign to vaccinate against smallpox. Some 5,000 are vaccinated each month. An inservice training program of teacher observation of the school child is to be inaugurated. The health habit card is to be developed.

Iraq

In Basra the first local health department in Iraq will train personnel to staff local health departments when established. Formal training is provided for sanitarians, health educators, and health visitors. The equivalent of a high school education is required for health visitors who then receive a year's training in nursery care, sanitation, personal hygiene, and school and child health.

Health visitors will be used in stead of nurses. Girls shun nursing

as a profession because of the still strong moral feeling against women taking part in public life. Health visitors must always go in pairs since a lone girl never enters a strange home. Only a few girls have been persuaded to enter this urgently needed field.

School health education depends largely on the success of the plan to assign health visitors to each school to carry on many of the functions of a school nurse.

Health instruction in Basra's two secondary schools, one for boys and one for girls, relates largely to the structure and function of the human body. Some sex education is included. Special emphasis is placed on diseases of the eye, malaria, and venereal disease. All secondary teachers must take 3 years of hygiene. Health instruction is not well established on the elementary level.

Lebanon

Lebanon epitomizes all of the school problems found in the other countries. Education is confronted with dual religious viewpoints (Moslem and Christian), dual educational philosophies (French Lebanese and American British), and dual education systems (government and private). Technical assistance has been limited to working with the public schools.

An important and popular school health project was instituted by the government in March 1953. Among other benefits, 150 public school teachers who had never attended any meetings of any kind during their career attended one of four regional school health conferences or a national conference held earlier.

The demonstration elementary school established outside Beirut in 1952 is the first in the Middle East in which both English speaking and Arabic speaking students are in attendance with equal privileges. A Lebanese nurse and a part time Lebanese pediatrician are employed. Each child has two physical examinations a year with followup home

visits. As a result of the home visits, some drastic changes in home sanitation and health consciousness have occurred.

Turkey

The Turks have better sanitation and water supply than most Asiatic countries. In the public schools, routine immunization against smallpox, diphtheria, and typhoid fever are given by the Ministry of Health.

The Turkish Tuberculosis Association gives the BCG immunizations and does the followup in home calls. Health instruction and physical education are both required in the junior and senior high schools. The girls' junior high school in Istanbul is the first Turkish school to use the modern community-oriented project type of school program, which was brought about by their parent-teacher association.

More important, he said, was the opportunity to extend the benefits of laboratory services to all: to have less concern about how many tests were done and more concern about how many who needed such a test did not receive it; less concern with the number of negative and positive tests and more concern with the number of false negatives and false positives; less concern with the number of tests available and more concern with their actual use. The criterion of community need would apply, he said, whether to cytological screening for uterine cancer or to toxicological detection services for industrial employees.

Laboratory Developments . . .

Focus on Community, Laboratories Urged

Public health laboratories, which have set the pace for public health programs in the past, have an opportunity to call the turn again, to shift the plane of focus from the microbe and the individual patient to the community as a whole, said Edward G. McGavran, M.D., M.P.H., dean of the School of Public Health, University of North Carolina.

Such a shift will support the attack on heart disease, cancer, mental disease, accidents, alcoholism, allergy, diabetes, glaucoma, rheumatism, and arthritis. It would promote the psychological and physical health of the environment, for both young and aged. It would stress rehabilitation no less than prevention, he said.

Changes in Practice

The present emphasis of public health laboratories on biological production and clinical examinations, he said, must be seen in historical perspective. The public health laboratories were born when clinical medicine shifted from the diagnosis of symptoms to the diagnosis of disease. As clinical science improved, and as investigations unfolded the complexities of the conflict among the forces of health and disease, at-

tention shifted from diagnosis of disease to diagnosis of man. The case of malaria or rheumatic fever, he said, became "an individual, a physical, emotional, and social entity." This shift was not one of function, service, or technique, but one of focus. Today, the focus is shifting again, he averred, to the scientific diagnosis and treatment of the community as an entity.

With such a shift in focus, the responsibility of the public health laboratory to the entire population implies certain specific changes in practice. Traditionally, public institutions provide for the needs of the people when private initiative is absent. As private enterprise grows to meet the need, public services are directed to other unmet needs. If it is not necessary for the health department to provide diagnostic services itself, it is still incumbent upon it to see that the private services provided are the best that can be supplied. If private laboratories are producing biologicals to meet the need, the public laboratory can then reduce its own output and give more attention to other community needs. Less time would then be given to direct laboratory service and more to supervision, licensing, consultation, and training to assure the excellence of laboratory services.

Community Diagnosis

To maintain their traditional leadership in public health practice, McGavran said, directors and key personnel in laboratories must be prepared to serve as "the doctor of the body politic." It is not sufficient for them to be experts in laboratory science. Beyond that essential background, they must know their community, its organization and power structure, its epidemiology and physiology. They must share in community diagnosis and know the resources and contributions of others in the public health profession. In short, they should be concerned first with public health and second with the laboratory.

It is a need among all disciplines in public health, he stated, to show less concern with their individual background, schooling, training, or origins and to show more concern with the job and status of the public health profession as a whole. It will not be easy to recruit qualified personnel for public health practice unless there is appreciation of the concept of public health as a calling in itself, he said. This concept of public health he pictured as "a distinctive profession of co-equal people from different disciplinary backgrounds with a specific focus on the community."

Such a concept challenges the best minds of young people in all health professions, he said, because ad-

vances in community or public health in the next hundred years will compare with advances of the past century in clinical sciences. But he said the challenge could not be voiced until those now working in public health accept the concept that theirs is a distinctive profession with a distinctive body of knowledge and a distinctive competence.

In essence, he said, that concept results in fixing the plane of focus on the community and treating the "patient community" as the "patient individual" hopes to be treated by a physician.

New Biochemical Methods Needed by Laboratories

The need for new biochemical techniques for diagnosis and investigation of diseases in possible emergencies as well as in normal circumstances was described by Gerald R. Cooper, M.D., Ph.D., chief, Hematology and Biochemistry Section, Communicable Disease Center, Public Health Service, Atlanta, Ga.

Needed particularly by the public health laboratory are specific and dependable diagnostic and screening tests for each disease, purified immunological and metabolic reagents for improvement of diagnostic tests, and methods for the detection of abnormal host resistance in communities. Other recommended fields of endeavor in biochemistry, he said, are standardization of, and training in, newly discovered tests and reference diagnosis in rare and exotic diseases.

Further studies of the biochemical nature of disease agents and of host reactions should lead to development of specific tests for all diseases, he said. He was of the opinion that rapid and specific identification of organisms might be accomplished by enzyme, fluorimetric, or infrared techniques, and that particular host reactions, especially metabolic, might be used to devise rapid diagnostic measures if such reactions could be determined.

Also, studies should be continued, he said, upon the biochemical reactions in diseases with altered or abnormal immune responses when no specific test is available to detect or to measure the pathology. Another test needed is one that can reveal sequelae or residual damage from diseases such as brucellosis and hepatitis.

He mentioned cat scratch fever, sarcoidosis, and amebiasis as examples of diseases for which dependable diagnostic and activity tests require purified antigenic material, particularly serologic and skin tests. If antigens, antibodies, and metabolic products could be isolated from impurities, many false test results could be prevented, he said.

Concerning the need for new means of detection and measurement of host resistance in communicable diseases, he called attention to the significance of gamma globulin. A high incidence of hypogammaglobulinemia in a population would indicate the possibility of abnormal spread of disease in epidemics and increase the extent of disaster under environmental stresses. This may be especially important in atomic bomb disasters, he said, explaining that both cellular and gamma globulin properties and content are altered by irradiation. Such alteration might make displaced persons abnormally susceptible to infectious agents.

Most pathologists have little time to train personnel and standardize performance of new biochemical tests. Cooper indicated that training such personnel and standardizing new tests, along with biochemical reference diagnosis in rare and exotic diseases, would represent a substantial contribution to laboratory medicine.

New *C. diphtheriae* Test May Help Small Labs

A test tube method for the determination of *Corynebacterium diphtheriae* toxigenicity has recently

been developed. It may be suitable both for mass testing and for performance in small laboratories unable to keep animals for fresh serum, according to Richard V. Walker, M.P.H., and Margaret I. Beattie, Dr.P.H., M.A., of the University of California School of Public Health, Berkeley, Calif.

Though all in vitro tests for *C. diphtheriae* virulence utilize the same ingredients, this simplification of conventional techniques takes less time and requires less antitoxin, serum, agar base, and material to be tested than petri dish versions. They said its sensitivity and specificity respectively were 98.4 percent and 98.9 percent, as ascertained by testing 190 strains previously tried in vivo.

A minimum 1.25 flocculating units per milliliter of preformed toxin were detectable. All components, except a minute amount of fresh serum agar, may be stored for 2 weeks prior to use, and most of the serum needed may be commercially prepared.

Described as patterned after a modification of the Oudin method for the detection of antigen-antibody reactions in agar gels, the new method employs a small test tube containing two layers of ingredients. The top layer is 0.4 ml. of 20-percent, fresh, unhemolyzed rabbit serum agar, into which reactants diffuse from an inoculum placed on its upper surface meniscus center and from the bottom layer. Five to six units of diphtheria antitoxin in 1.00 ml. of 20-percent normal rabbit or horse serum agar constitutes the bottom layer, and the inoculum consists of *C. diphtheriae* organisms of suspected toxigenicity.

If toxin is produced by these organisms, concentrations of toxin and antitoxin increase independently in the diffusion zone. A white disc of precipitate appears where the ratio of these concentrations first approximates an optimum for flocculation. The test is positive if this occurs within 48 hours after inoculation of the tube medium.

The inoculum is obtained by pushing the circular part of a bacteriological loop, bent to form a right angle with the shaft of the instrument, over the surface of Loeffler's medium cultures or from colonies on blood-tellurite agar plates. In the latter case, a wire inoculating needle with an almost 90° bend one-eighth of an inch from the tip is used.

Walker and Beattie found that the inoculation must be accomplished by touching without breaking the surface of the test medium. This technique, however, affords a thinner margin for error than analogous, streaking procedures in earlier test processes.

They also agreed other technical difficulties inherent in the test might be reduced by centrifuging constituents for clarity when necessary, by assuring the sterility of the antitoxin reservoir serum, and by retesting negative strains *in vivo*.

New Techniques Step Up Smallpox Vaccine Output

Yields of avianized smallpox vaccine have been increased threefold and the processing time has been reduced by recent changes in production methods.

Reporting the new techniques were Philip J. Forsyth, M.A., and E. B. M. Cook, M.A., immunologists with the Texas State Department of Health, Austin.

Injection of the seed virus directly into the allantoic cavity of an embryonated egg through the air sac end produces vaccinal lesions that are scattered throughout the chorio-allantoic membrane, and the entire membrane can be harvested for vaccine use, they reported.

In the Reid method of creating a false air sac over the embryo and injecting the seed virus into the "dropped" area, only a small portion of the membrane, 20 by 30 mm., was infected and harvested.

The average amount of vaccine produced per egg inoculated by the

old method was 1.5 ml. By the allantoic cavity method, the average yield is 5.2 ml. of vaccine—an increase of from 60 to 200 individual vaccinations per egg, they said.

The allantoic inoculation process is also a time and work saver, they reported. Done quickly and easily with an automatic pipetting machine, it takes only 6 man-hours to inoculate 600 embryos compared to the 24 to 30 man-hours for the Reid method.

Definitive Potency Test

Tying in with increased vaccine volume was a suggested method of measuring more accurately the potency of the harvested vaccine, thus allowing more definitive dilution at a considerable saving in the manufacture.

Egg titration, they said, provides an accurate measure of the number of infectious particles of virus present in a given lot of vaccine. Specially prepared and diluted vaccine material is inoculated onto the chorio-allantoic membrane of 11- to 12-day-old embryonated eggs by the triangular-flap method. After a 3-day incubation period, the infected portions of the membranes disclose large and easily counted pocks under a dissecting microscope. Each pock is assumed to be the result of the growth of one infectious particle of vaccinia virus. The average number of pocks present for each dilution inoculated is determined, and from these counts the number of infectious particles present, or the titer of the original material, is calculated.

With a vaccine of known and predictable strength, the vaccine pulp material can be diluted as required, they said. It is now common practice, they explained, to dilute all vaccine pulp 1:5, regardless of the actual virus titer. Under this arbitrary dilution method, much of the vaccine greatly exceeds the required strength or fails to pass the standard potency test and must be discarded.

In their experiments, Forsyth and Cook found that a virus concentra-

tion of 20 million infectious particles per milliliter of vaccine suspension, read by the egg titration method, was successful in every Force and Leake rabbit scarification test. The rabbit test is the established method of testing vaccine potency.

On the basis of egg titration results, they were able, in many instances, to dilute infected membrane up to 1:20 and thus increase the vaccine from twofold to fourfold.

The avianized vaccinia virus retains its stability equally well in dilute and in concentrated form, they found.

Three Trichinosis Tests Are Rated in Study

The complement fixation and flocculation tests for trichinosis were found to give comparable and valuable results superior to the precipitin test, according to four members of New York City's Health Department.

Harold T. Fuerst, M.D., epidemiologist, Morris Greenberg, M.D., director, bureau of preventable disease, and Daniel Widelock, Ph.D., assistant director, and Annie E. Thomson, M.D., bacteriologist, bureau of laboratories, conducted the investigations.

The choice of either the complement fixation or flocculation test, or both in combination, may be based on individual considerations, they said, although the use of the two tests in combination does not generally increase diagnostic accuracy. However, they continued, when one test is doubtful, a positive or negative result with the other may aid in appraising the clinical findings.

Study Conditions

During 1952 to 1954, concurrent determinations of complement fixation and flocculation tests for trichinosis were performed on 437 serum samples submitted from 243 persons with active trichinosis and on 425 serum samples from 343 persons with no clinical evidence of the disease. The presence or absence of trichino-

sis in the 586 persons was verified by epidemiological investigations, they explained.

Single serum samples submitted for routine tests for syphilis from 321 persons were also tested for trichinosis by the two tests as controls, they stated. No clinical or epidemiological investigation of this group was made, they said.

Among the 343 persons whose clinical diagnosis showed no infection, 69 percent of the complement fixation tests and 65 percent of the flocculation tests were persistently negative, they related. Of the 243 persons with trichinosis, 64 percent of the complement fixation tests and 59 percent of the flocculation tests gave four-plus results. The differences between the tests were not statistically significant, they said.

Titers from plus-minus to three-plus inclusive, have little, if any, diagnostic significance. The percentage of such intermediate reactors was consistently greater with the flocculation test than with complement fixation, they reported.

Maximum reactivity with the two tests appeared at the fifth to sixth week after the onset of trichinosis. The specificity of either of the two tests was markedly better than for the precipitin test, they declared.

Biological False Positives Found by New TPCF Test

A new test may soon provide State laboratories with a simple method for detecting biological false positive reactions in serum tests for syphilis, reported Harold J. Magnuson, M.D., M.P.H., chief, Operational Research Section, Venereal Disease Program, Public Health Service, and Joseph Portnoy, Ph.D., bacteriologist, Venereal Disease Experimental Laboratory, Chapel Hill, N.C. Magnuson and Portnoy believe that the new test "will be as helpful as any other single test procedure now available."

The new *Treponema pallidum* complement fixation test (TPCF) appar-

ently is as specific as the tests in general use, Magnuson and Portnoy stated. No single test technique will measure all of the antibodies of syphilis, they said, but one or more of the treponemal tests may reduce the margin of diagnostic error, even though they will never eliminate it.

The principle of the test, they said, is simple. Virulent *T. pallidum* is obtained from infected rabbit testes, and the treponemes are concentrated by differential centrifugation. The lipid fractions are removed by successive acetone and ether extractions, and the active proteinlike antigen is then removed from the dried treponemes by a 0.2 percent solution of sodium desoxycholate. The resultant antigen is used in a conventional complement fixation test similar to the fifth volume Kolmer technique.

Test Sensitivity

In primary and secondary syphilis and in congenital syphilis, the TPCF test was more reactive than the *Treponema pallidum* immobilization (TPI) test, in syphilis of the central nervous system, the TPI test was more reactive than the TPCF test, and in latent and cardiovascular syphilis, the tests were about equally sensitive, Magnuson and Portnoy reported.

They said that, in 266 patients assumed to have biological false positive reactions, serologic tests for syphilis (STS), TPI, and TPCF tests agreed in only 33.5 percent of the cases, but the TPI and TPCF tests agreed in 94 percent. In 78 "definite" false positive reactors, TPI and TPCF tests agreed in 98.7 percent of the cases, and agreement between the two tests among 188 possible false positive reactors was 92 percent.

In untreated early syphilis, TPCF and STS results were somewhat parallel, in the later stages of the disease, the correlation between results of TPI and TPCF tests was much higher than between either treponemal test and STS, Magnuson and Portnoy stated. They emphasized, however, that neither treponemal

test measures reagin, so that correlation between TPCF and STS results is not due to reagin cross reactivity.

In treated early syphilis, the correlation between TPCF and TPI tests is somewhat greater than the correlation between the treponemal tests and STS. In treated late syphilis, agreement between the two treponemal tests was less satisfactory than in untreated late syphilis.

Magnuson and Portnoy reported that two manufacturers are beginning to produce TPCF antigen and that as soon as the antigen is more generally available, evaluation of the test will advance more rapidly.

In conclusion, they said that if the present trends of production continue, any well-run laboratory will be able to perform the TPCF test and that "the results should be highly useful to State laboratories and clinicians in helping to resolve some of the perplexing diagnostic problems that arise in the serodiagnosis of syphilis."

Study Shows Reliability Of STS and TPI Tests

The reliability of standard serologic tests for syphilis (STS) and the value of the *Treponema pallidum* immobilization (TPI) test in so-called questionable cases of syphilis were confirmed by a study conducted at the University of Michigan Hospital.

The study and conclusions were reported by Elizabeth B. McDermott, Lenon B. Stewart, M.S., and Reuben L. Kahn, Sc.D., of the serologic laboratory, and Albert H. Wheeler, D.P.H., and Ella M. Brandon, A.B., of the TPI research laboratory, department of dermatology and syphilology, University Hospital, University of Michigan, Ann Arbor, Mich.

Various laboratory workers have reported that when clinical findings and STS results do not agree, as many as 40 percent of positive STS have been negative by the TPI test. These findings led to the belief that standard blood tests gave large num-

bers of false-positive results and hence were not reliable.

Kahn vs. TPI Test

At the University Hospital, where the Kahn test is used routinely, TPI tests are done free of charge whenever they are requested by the physician, McDermott and her associates said. Between September 16, 1954, and July 1, 1955, requests were received for TPI tests in 78 of 31,545 cases on which Kahn tests had been done. The results of these tests were:

Kahn positive, TPI negative....	23
Kahn negative, TPI positive....	6
Inconclusive (TPI and Kahn)....	10
Agreement between Kahn and TPI tests.....	39

The 23 false-positive tests, 29 percent of the 78 tests performed, indicate that the TPI test is a valuable supplement to standard blood tests when clinical findings and standard blood tests disagree, the research group stated. However, these same 23 false-positive reactions represent only 0.07 percent of the 31,545 cases tested, which in turn indicates that the standard blood tests are highly reliable in routine medical practice. The six Kahn negative-TPI positive reports cannot all be considered as false negatives, they said, "in view of the persistent positivity of the TPI tests in long-standing, adequately treated cases."

False Positives

There is a continuing need for watchfulness for false-positive reactions, they stated. Many false-positive reactors who have been under observation for a number of years have been diagnosed as either syphilitic or nonsyphilitic in the 6 years since the TPI test became available, and a decrease in the incidence of suspected false-positive serologic reactions may be expected from now on. However, the reduction in the prevalence of syphilis may be resulting in an apparent rise in positive blood test results in nonsyphilitic cases, they warned.

They also emphasized that false-positive reactions are false only in relation to syphilis. Such reactions may have clinical value in other diseases, particularly in the collagen diseases, such as disseminated lupus erythematosus, periarteritis nodosa, rheumatoid arthritis, and rheumatic fever, they concluded.

Minnesota Study Compares Bacteria Count Methods

The standard plate count (SPC) is a more rigorous and discriminating bacteriological test for grading raw milk than either the direct mi-

croscopic count (DMC) or the laboratory pasteurized count (LPC), according to results of a study made in the Minneapolis-St. Paul milk shed.

James J. Jezeski, Ph.D., and J. C. Olson, Jr., Ph.D., associate professors of bacteriology, department of dairy husbandry, University of Minnesota, and W. C. Lawton, Ph.D., laboratory director, Minneapolis-St. Paul Quality Control Committee, reported on the comparative studies to determine whether the LPC alone could be used for grading raw milk.

On the basis of 7,949 milk samples from about 750 producers between

Relative agreement between three grading methods in the detection of unsatisfactory milk samples, Minneapolis-St. Paul milk shed, June 1954-May 1955

Period	Number unsatisfactory by—	Detected by—			
		SPC ²		LPC ³

¹ Direct microscopic count.

² Standard plate count.

³ Laboratory pasteurized count.

June 1954 and May 1955 collected at monthly intervals, they reported the SPC at 200,000 bacteria per ml. detected 13.6 percent of the unsatisfactory samples, DMC at 200,000 per ml., 3.7 percent, and LPC at 30,000 per ml. detected 5.4 percent.

Of the 1,329 samples unsatisfactory by any one or the various combinations of methods, SPC detected 81 percent; DMC, 22 percent; and LPC, 32 percent. SPC provided the best detection of various types of unsatisfactory samples and was considered to be the only method which might be used as a sole grading test, they commented.

The relative agreement between the three methods and seasonal variations are shown in the table. Using the various paired combinations, the SPC-LPC combination missed 3.2 percent of the unsatisfactory samples, DMC-LPC missed 50 percent, and DMC-SPC missed 15 percent, they said.

Methodology and Results

All tests and procedures followed the *Standard Methods for the Examination of Dairy Products*, 10th edition. Samples were taken directly from the weigh tank as the milk was received. DMC slides were counted with microscopes having a 500,000 factor, with 50 fields counted routinely.

Further detailed studies to confirm or refute the data from this study are needed, they declared. Serious consideration should be given to: (a) the true worth of the direct microscopic count; (b) the establishment of rigidly controlled studies to determine the efficiency of the laboratory pasteurized count in other milk sheds; (c) the question of whether a sole LPC grading program would result in a materially increased product quality, and (d) the question of whether an LPC grading program alone would impose unnecessary burdens on the producer.

Reducing the LPC grade level below 30,000 will result in the detection of more unsatisfactory SPC samples, but the LPC standard must

be reduced below 5,000 to detect about 50 percent of the unsatisfactory SPC samples, they asserted.

Phosphate-Bearing Water No Obstacle to New Test

A method for determining fluoride concentrations ranging from 0.2 to 2.0 p.p.m. in water supplies containing phosphates up to 2.0 p.p.m. was reported by the laboratory services section of the Connecticut State Department of Health, Hartford.

According to Earle K. Borman, M.S., chief of the section, and chemists Barbara G. Lang, B.S., and Omer C. Sieverding, B.S., the Connecticut test has a higher degree of accuracy than older methods.

Another advantage over the Lamar test, most widely used in regulating fluoridation operations, is that minor variations in room temperature do not affect the rapid development of maximum color in the samples.

Although both tests are subject to interference from substances other than phosphates, the Lamar test, a modification of the zirconium-all-zarin determination, is not sufficiently accurate, even after a single distillation of the sample, to permit reliable assay of fluoride concentrations which depart by more than 10 percent from 1 p.p.m. when phosphates are present. Furthermore,

any drop below 1.0 p.p.m. in fluoride content introduces additional errors in the Lamar test when the phosphate content is as high as 0.5 p.p.m.

The new test was described as based upon the titration of unbound thorium using chrome azurol S indicator. Five milliliters each of indicator and buffered thorium nitrate solution are added to a 50 ml. aliquot sample in a Nessler tube. The color so obtained is suitable for spectrophotometric determination of the aliquot. This is accomplished by comparing its transmission value at 595 m μ with those on a curve plotting such values for solutions of known fluoride concentrations ranging from 0.2 to 2.0 p.p.m.

The buffered thorium nitrate solution consists of 4.75 parts buffer solution and 0.25 parts thorium nitrate solution. The buffer solution is prepared by diluting 22.7 gm. monochloroacetic acid with 4.8 gm. sodium hydroxide to 1,000 ml. The thorium nitrate solution is 3.5000 gm. thorium nitrate tetrahydrate diluted to 500 ml. It was emphasized that the success of the test is contingent upon the precision attained in measuring this latter reagent. Thorium nitrate must remain in excess after reaction with the fluoride ion.

If a spectrophotometer is not available, aliquots may be compared on a color basis to freshly standardized knowns.

Medical Economics . . .

Improve Or Be Replaced Hospitals Advised

As chief of the Nation's largest municipal hospital system, Basil C. MacLean, M.D., commissioner of hospitals, New York City, advised voluntary hospitals that unless they improved their organizations and

public services they would be supplanted more and more by governmental institutions. Although he himself favors a continuing partnership of government with voluntary institutions, he said, the continuance of that partnership depends on fuller recognition by the voluntary institutions of their public obligations.

The budget of his own municipal department includes more than \$100 million annually for operating city institutions and \$20 million for the care of public charges in voluntary hospitals. In the past 20 years, the city contribution to voluntary hospitals for its "so-called" charges, he said, has increased from \$2.75 to \$14 a day, and there is pressure to raise the amount to approximate more nearly their ward costs of \$20 a day or more.

The "sagging economy" of the voluntary hospitals has been supported by the growth of the voluntary health insurance plans, he said, but it has not spared them from the necessity of seeking still further government aid. To warrant such support, with the passing of "the tin-cup method of meeting hospital deficits," he said that voluntary institutions will be obliged to operate in a businesslike way to provide health services at a reasonable cost.

A Public Voice

He challenged the notion that the tax-exempt status of the hospital derives from its "nonprofit" status rather than from the extent of community service offered. Considering that the public investment in hospitals amounts to more than \$50,000 for each licensed doctor in the United States, he questioned the right of the medical entrepreneur to set policies in voluntary hospitals without public interference and to deny the public a voice in determining prices and methods of payment of hospital services.

Admission policies also received heavy criticism from the commissioner. He charged that even when there is no question of compensation from the city or from insurance plans, the resident staff often rejects interesting and obscure cases in favor of more glamorous but simple surgical cases which assuage the "scalpel itch."

Multiple bills and fees associated with hospital services were compared by MacLean to the outmoded fashion of paying separate tuition fees to each professor in the medical

CHRONIC DISEASES RISE INFECTIOUS DISEASES DECLINE

DEATHS PER 100,000

school. "Those who insist on a \$5 bill passing from the patient to a doctor for each urinalysis done by a technician," he said, "are pushing the public to demand governmental control." He said the public is disturbed by squabbles over what is and what is not hospital care and "by the confusion and cost of a system in which the doctor competes with the hospital for the patient's pocketbook."

"More and more," he asserted, "the question is being asked—whom does the voluntary hospital actually serve—the patient or doctor?"

Chronic Services

To justify additional governmental help, he recommended that voluntary hospitals be willing to admit a fair load of medically indigent cases even if city subsidy does not meet the full cost. He said they must also give thought to establishing wings or annexes for chronic patients, including those with cancer and mental illness, with provisions not only for teaching material but for terminal cases. Otherwise, he warned, a further assumption of such responsibilities by government will ensue.

It makes more sense, he said, for cities to keep voluntary hospitals functioning effectively than to compete with them. "Government should step in only when voluntary effort fails," he said, "but it must be honest voluntary effort, dedicated to public service . . . and not controlled by predatory interests."

HIP Evaluates Its Services, Grades Quality of Care

The scoring system developed in the HIP evaluation of group practice clearly identifies the physician who provides good medical care, according to Edwin F. Daily, M.D., and Mildred A. Morehead, M.D., M.P.H., vice-president and associate medical director, respectively, Health Insurance Plan of Greater New York.

To date, 18 of the 29 medical groups affiliated with HIP have been evaluated in the study, which began in 1954.

The HIP evaluation produces an objective evaluation of the management of selected cases of serious illness by an impartial review and dis-

cussion of clinical records, Daily and Morehead reported. Altogether, 80 percent of the plan's services will be assessed.

As a result of classifying group physicians according to average scores within the point ranges of 76-100 (good), 61-75 (adequate), 46-60 (below average), or 0-45 (poor), the services of some physicians with low ratings have been terminated, so effective is the index, Daily and Morehead also reported. They believe it can be adapted to other medical care plans.

Basic Factors

The basic problem in methodology, the HIP officers explained, was to determine the type of material to be studied, the criteria for evaluation, the methods of recording information, and the relative weights to be given to the various factors. The cases selected for study are those in which the diagnosis on record at the central HIP office suggests the need for fairly extensive diagnostic work-up.

The evaluation encompasses a review of the clinical records in the departments of medicine, surgery, obstetrics-gynecology, and pediatrics within each medical group. Evaluation of radiology and pathology departments includes reviewing X-ray films and the group radiologist's reports and reviewing pathology charts and procedures as well as making control comparisons of specimens and tests. Study of preventive services is based on the presence or absence of expected preventive procedures.

A recognized specialist who is not affiliated with HIP visits the group physician's office, taking with him a list of the patients whose case management he intends to analyze. He reviews the clinical records, guided by criteria for evaluating the items to be rated, then rates and summarizes the handling of each case on a case work card. The possible ratings *a*, *b*, and *c* correspond to satisfactory, fair, and poor.

The interviewer credits the group physician for any information he may add during their subsequent discussion of each case, when the physician is also questioned about hospitalization policies, workloads, hours on call, and other factors influencing the operation of the group in which he practices.

Scores Averaged

The clinical material obtained from the case studies and the interviewer's ratings are checked for accuracy, and numerical weights for scoring are assigned to the case work evaluations. The maximum possible score for the management of a single case, 100, is distributed among the three major areas studied for each case: 30 for the records section on the case card, 40 for diagnostic workup, 30 for treatment and follow-up.

At the conclusion of the study of each medical group, the scores are averaged, to obtain ratings for each physician, each department, and each group. Findings show that the averages of the scores provide an effective index for comparing medical groups and services. When the separate scores for any of the 16 items on the case card are averaged item-wise, they reveal areas of strength and weakness within the medical group. The range of scores for the cases of each physician is generally narrow.

The study does not end with the analysis of the scores. It continues with special presentations of findings at several evening sessions for all members of the medical group and with an intensive followup by a special team of consultants who advise the group's executive committee on how to carry out the specific recommendations of the medical team.

As a result of the study, many specific examples of improved methods of practice by individual physicians have been noted. Improved use of consultation and diagnostic services available in group practice have been repeatedly observed. A better understanding of the potentialities of

teamwork in group practice is also evident.

All recommendations concerning laboratory and X-ray departments, usually minor, have been promptly corrected. Rechecks of clinical records a few months after evaluation show much improvement. Chiefs of the various departments, some for the first time, have assumed full responsibility for directing the work of their associates and integrating their service with other departments.

The cost of the study has been about \$60,000 per year or about 15 cents per insured person. Future studies should take into consideration such factors as investigation of more cases of minor illness to determine if more serious illness existed, changes in scoring so that an unsatisfactory grade in one category would prevent full credit in the other two, direct observation of a physician's work, evaluation of doctor-patient relationships, and average time per office service.

Care of Long-Term Illness Will Require New Funds

Adequate care of patients with chronic illnesses cannot be financed entirely from personal savings, nor will redistribution of existing funds for personal health services be sufficient to cover the cost of medical care for this group.

New money must be provided through higher insurance premiums from currently insured individuals, larger contributions by employers, and subsidies from various levels of government.

These were the points emphasized by Odin W. Anderson, Ph.D., research director, Health Information Foundation, New York, N. Y., in his discussion of the complex problems in financing long-term illness.

The recent increase in queries about the cost of treating diseases such as cancer and poliomyelitis seems to indicate that the problems accompanying them are becoming so

pressing that consideration is now being given to particular chronic diseases as well as to age groups and other special groups in the population, Anderson stated.

He based his discussion on the following assumptions and observations gleaned from the literature and recent conferences on chronic illness:

1. No family should be forced to reduce drastically its usual standard of living because of the cost of personal health services. Adequate insurance coverage should be available to self-sustaining families to meet such unpredictable costs.

2. At present families must be reduced to a subsistence level before they can benefit from tax-supported medical care programs. If a normally self-sustaining family above subsistence level is to remain self-sustaining, it must have access to adequate health insurance.

3. Long-term illness, a characteristic of the growing population over 50 years of age, has increased greatly during the past 50 years. Existing facilities, professional health personnel, and organization methods are not geared to the complex problems of long-term illness.

4. Similarly, except for certain illnesses such as tuberculosis and mental disease, existing methods of financing are not geared to the care of the patient with long-term illness.

5. Adequate services for the care of these patients cannot be financed from savings—liquid assets, personal property, and other personal effects—and from other assets which are regarded as the birthright of American citizens.

6. The prevailing benefits of voluntary health insurance today are hospital care and physicians' services in the hospital. For long-term illness, a broad range of services considerably beyond these benefits needs to be provided and financed.

7. Long-term illness is always expensive. The expense will be borne by the patient, his family, the insured group, or the total population through taxes.

8. Long-term illness involves loss of income if the wage earner is ill, expenditures for medical care, and additional expenditures for personal needs or services. Loss of income is proportionately a larger consideration in a long-term illness than in a short-term illness.

9. Because long-term illnesses have a relatively low incidence, it is more difficult to interest individuals in the need for insurance to cover costs of these expensive illnesses than in insurance for short-term illnesses.

10. Voluntary health insurance agencies are experimenting with major medical contracts to cover the costs of expensive illness, including long-term illness. Expansion of such contracts for employed persons can be expected to increase.

11. New mechanisms are needed and are being explored to underwrite adequate health insurance for usually ineligible, high-risk groups, such as the aged and the indigent.

12. New money will be required to finance adequate health services, and a redistribution of existing expenditures for personal health services will not be sufficient.

13. Therefore, higher premiums from currently insured persons, larger contributions from employers, and subsidies from various levels of government will be necessary.

14. During the next 10 years, major emphasis should be on increasing available finances for the care of patients with long-term illness. Reorganization of services may follow but will take longer. The amount and methods of financing and of organizing and providing services are directly related.

Present Costs

Costs for medical care range from 0 to 50 percent of family income and average approximately 5 percent of family income, Anderson reported. The lower the income, the larger the percentage spent for personal health services, Anderson pointed out.

At present, the annual cost of personal health services averages \$207 per family, Anderson stated. Some costs for chronic illness are undoubtedly included in this figure, he said, although it is impossible to separate them from the total. However, 16 percent of the total costs for all families were in amounts of \$400 and over, distributed as follows:

<i>Medical costs in excess of—</i>	<i>Percent of families</i>
\$400-----	16
500-----	11
750-----	4
1,000-----	2

Distribution of the families whose expense for medical care exceeded \$1,000, by family income, was:

<i>Annual Income</i>	<i>Medical expense over \$1,000 (percent)</i>
Under \$2,000-----	1
\$2,000-3,499 -----	1
3,500-4,999 -----	2
5,000-7,499 -----	2
7,500 and over-----	5

Approaches to the Problem

Anderson discussed some possible approaches to the care of persons with long-term, costly illnesses. Among these were increasing the range of benefits in existing voluntary health insurance. At present, even the most comprehensive hospital and medical care plans do not provide home nursing service, convalescent home care, and appliances, he said. Also, with the possible exception of some major medical contracts, these plans frequently do not provide drugs.

If \$10 per family could be directed into health services, through health insurance or by some other means, it would mean \$500 million in new money for the care of patients with chronic illness; \$20 per family would increase the amount to \$1 billion, Anderson estimated.

We have a fair idea of the distribution of costs of personal health services among families of varying incomes in this country and of the proportions of these families whose

costs are above certain amounts, Anderson stated. However, he said that he had no way of knowing or estimating how much it would cost to provide the full range of services necessary to care for chronically ill persons if the funds and facilities were available to establish a full-scale program.

"Lack of experience inhibits action since financial considerations are a potent factor in trying new ventures; someone has to risk the capital," he concluded.

Federal-State Aid Program For the Needy Reviewed

In a review of Federal participation in medical care for the needy, Charles I. Schottland, commissioner of Social Security, compared the volume of need with the amount of assistance given.

Of the nearly 5 million persons now benefiting from Federal financial aid to the States under the four assistance programs, a large proportion have an extraordinary volume of medical needs as a result of disability, chronic illness, or the infirmities of old age, he pointed out.

The estimated present medical care expenditures from Federal, State, and local funds total approximately \$265 million annually, or an average of about \$52 a year, for each assistance recipient in the four categories, he said.

For the average population, he reported, Blue Cross and Blue Shield insurance premiums covering hospitalization and in-hospital surgical and medical care would amount to at least \$100. And in 1954, each man, woman, and child accounted for \$63.25 worth of private medical care, excluding services paid from tax funds.

In describing the present formula for old-age assistance, aid to the blind, and aid to permanently and totally disabled persons, Schottland reminded that the maximum amount

in which the Federal Government may participate is set at \$55 per person a month for all needs. Within this maximum, the Federal share is four-fifths of the first \$25 and one-half of the remainder, or \$35 on the maximum. (The maximum in the aid to dependent children program varies with the size of the family.)

If a substantial medical cost is paid in any one month, the total of maintenance and medical care is likely to exceed \$55, with the result that Federal participation in medical care is very limited, he said.

He named as another problem the complex and relatively costly book-keeping operation in computing the Federal and State shares for each recipient.

State Programs

In discussing the State programs, Schottland reported that an analysis of the situation in 48 States, the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands reveals that 7 States make no payments for medical care under the four categories; 1 State provides this care through its public health department; and in the remaining 45 States the average annual expenditure per person receiving assistance is under \$24 for 20 States; \$24-\$71.99 for 15; and \$72 or more for 10 States.

Each State determines what items are necessary and how much will be paid for them, Schottland reported. Most of the States have limitations on the kind or amount of medical care provided from assistance funds. Some States make no provision for hospital or nursing home care; others provide only for hospitalization and drugs. One State provides dentures only to employable persons. In a number of States the funds allowed for dental care or for glasses or appliances that might help rehabilitate the recipient are severely limited. Still others limit the number of doctors' calls that will be paid for or the total amount allowed for medical care.

A number of proposals, he said, have been advanced from time to time to encourage and assist in the provision of adequate medical care by empowering separate matching of medical care expenditures.

Practicable Hospital Data Goal of New Audit Plan

A new medical audit method for assessing hospital services has emerged from the research work of the American College of Surgeons and the Professional Activity Study of the Southwestern Michigan Hospital Council.

Paul R. Hawley, M.D., director of the American College of Surgeons, reported that the new approach has proved effective, practicable, and inexpensive in intensive testing at 23 hospitals in 21 communities in 3 States.

He named as deficiencies in past medical audits: use of nonvalid statistics, such as the discharge conditions of "recovered" and "improved"; surveys of limited and non-conclusive criteria, such as infections and deaths; impracticable methods of collecting, tabulating, and analyzing the data selected; and demands for excessive participation by busy practicing physicians.

In a civilization noted for its ability to enumerate the yearly production of automobiles, cans of soup, and bars of soap, we have no exact statistical information about such fundamentals as the number of appendectomies performed or the number of pneumonia patients treated in our hospitals each year. Hawley said.

The Procedure

Basic to the new system are useful data standardized to permit comparison among hospitals of like size and patient groups, machine tabulation and analysis by a regional statistical service, and hospital medical staff evaluation.

Diabetes patients without blood sugar determinations.

From the hospital's medical records on discharged patients, the record room librarian transfers to a code sheet the data selected for analysis and comparison. Entered are such facts as the patient's age and sex, patient's physician, final diagnosis, operations, and laboratory procedures. For instance, if a blood count was done, this fact is recorded on the code sheet. If a chest X-ray or urinalysis was not made, this fact is recorded. The medical room librarian has no further responsibility for indexing and statistical presentation.

The code sheets go to a regional statistical service center where the

data are put on punchcards and machine tabulated. Five different kinds of lists are run off, breaking the data down by diagnosis, operation, physician, surgeon, and clinical service. The lists are returned to the individual hospitals and provide the medical record indexes necessary for accreditation.

With the data of all the participating hospitals retained on punchcards, the center can produce analytical comparisons in any specified phase.

Comparative analysis of medical care for the same disease gives the individual hospital a yardstick for measuring its practices and, if the pattern of care varies widely from

the other hospitals, the opportunity to determine the reasons, Hawley said. Medical staff evaluation of selected phases of patient care, he indicated, permits an effective and timesaving spot check by physicians.

The Result

He drew several sample evaluation situations from the trial test results. One was the varying practice among 15 community hospitals of making blood sugar determinations on diabetes patients (see chart). Each of the hospitals had adequate laboratory facilities and were in an area noted for above average medical care. But in 8 of these hospitals at least 10 percent of the patients with recorded diabetes received no blood sugar determinations during their hospital stay.

The medical staffs of these hospitals, he commented, would certainly be interested in ascertaining the reasons for failure to use such a recognized, established, and authoritative test in the diagnosis and treatment of diabetes.

Hawley concluded that the presentation of statistical evidence on hospital services and experience emphasizes facts missed entirely by methods of evaluation that fail to tabulate, analyze, and compare practices.

Metropolis O. K.'s Care But Not Way It's Given

The people of "Metropolis" tend to be satisfied with what they get in the way of medical care and to accept its cost, but they dislike the impersonality with which it is given, according to Earl Lomon Koos, Ph.D., professor of social welfare, Florida State University.

That modern, technique-centered medical practice lacks the human warmth of the old-time general practitioner was the view of 64 percent of 1,000 families, he stated.

Families in which husbands were under 40 years of age were more def-

nite in their criticism than were families in which husbands were older. This finding, Koos said, disagrees with the charge that this attitude exists only among the older age groups, who view the passing of the family doctor with nostalgia.

Only 19 percent of the families believed that medical care was too expensive, and only 17 percent expressed pronounced dissatisfaction with the care available or received.

Koos described "Metropolis" as a somewhat sophisticated city of about 350,000 population located in the industrial northeastern United States. It has a medical school, a half dozen approved hospitals, a full complement of medical specialists, a sprinkling of general practitioners, and an "above average" health department. It may not be entirely representative of cities of its size, but it is probably nearly so, Koos said.

The families interviewed were an economically stratified but randomly selected sample. Data were analyzed on the basis of the family's membership in 1 of 3 social strata.

It is futile to belabor the physicians of "Metropolis" for they are often caught in a social matrix not of their own making, Koos said. However, it should not be futile, he added, to suggest that the individual physician alter his techniques and attitudes, insofar as possible, to provide what the people feel they need and want from medical care.

Hospital Care

A somewhat similar but less specific criticism was made against hospital care, Koos indicated. Seventy-one percent of the respondents believed that the hospital care available to them was unsatisfactory, but most of them were not quite sure why. Koos said the following excerpt from one interview was characteristic of the replies of 8 out of 10 of those dissatisfied:

"I don't say our hospitals don't turn you out alive . . . but the way they treat you while you are in their

hands is pitiful. . . . I can't put my finger on it exactly. I think what I'm trying to say is nobody just gave a darn about me as a person. I was just somebody filling a bed."

Koos believes this situation is the result of the hospitals' changing social structure. The replacement of the relatively simple hierarchy of doctor-nurse-orderly-kitchen maid with a structure which includes various aides, technicians, floor clerks, and so on has created confusion and frustration for the patient and his family, he said.

Eighty-two percent of the families also believed that hospital costs were too high.

It must be admitted that the hospital, like the physician, is caught in the coils of an advancing medical technology, as well as faced with problems of labor and economics, Koos noted. He believes, however, that many of the ills current in hospital-patient-family relations are present simply because the patient has been somewhat forgotten.

Public Health

The health department was viewed as a sort of health police force, Koos reported. Such functions as "keeping the water pure," "being sure that sewage is taken care of," "quarantining people who have infected [sic] diseases," "being sure that the restaurants are clean," were considered the only functions of the health department by two-thirds of the families.

There was little consciousness of the health department's value, its effectiveness, or even its real functions, he declared.

Koos suggested that one answer to why community health programs have not progressed more rapidly may be found in these data. If the population of a sophisticated urban community of better than average economic status lacks knowledge and appreciation of its health department's activities, we may well expect a similar or even greater lack in less-advantaged communities, he said.

When asked to suggest health needs not now being met that might be met through health department activities, only 2 to 3 percent gave fruitful answers.

The results of this study, according to Koos, suggest either a magnificent complacency about the health of the community, or an acute unawareness of what the term "health" really means, or an unawareness of what public health personnel have to offer. He believes that any of the three explanations gives cause to be disturbed.

Saskatchewan's Experience With Prepaid Care

In Saskatchewan, Canada, three separate patterns of prepaid medical care have evolved over the past 35 years. The strengths and weaknesses of each in meeting the problems of rural medical care and possible further developments were discussed by Milton I. Roemer, M.D., M.P.H., director of the medical and hospital services branch, Saskatchewan Department of Public Health, Regina, Canada.

The first pattern was the municipal doctor plan, according to Roemer. Although varying in detail in different municipalities, the plan is essentially this: In return for a salary, paid from local tax funds (in later years, supplemented by provincial grants), a physician provides medical services to any resident of the municipality needing them.

Developed entirely through local initiative, the municipal doctor plans are the prairie settlers' answer to the problem of attracting and holding physicians in rural communities, he stated. And to this end, he specified, they have been effective. By 1950, the peak year, there were 173 municipal plans in operation, covering at least 200,000 of the Province's 833,000 population.

These plans, however, have not been able to keep pace with changes in social and living conditions or in

the practice of medicine, Roemer maintained. The inability of an isolated general practitioner to practice the best modern medicine he considers the most serious limitation.

Neither the quality nor the quantity of services provided under the municipal doctor plans can be a cause for deep satisfaction, he said. Concerning quantity, he mentioned that in one plan the volume of services in 1951 was 1,883 per 1,000 persons. In this plan, there were 2 physicians practicing full time and 3 who were semiretired, serving 3,000 persons. He compared the figure to the 4,405 services per 1,000 persons provided in the same year under the regional medical care program in the Swift Current public health region, where there were 36 physicians for a population of about 50,000.

Voluntary Plans

Voluntary prepayment plans sponsored by the physicians themselves was the second of the patterns. Begun in 1939 in the cities of Saskatoon and Regina, where local governmental prepayment plans did not exist, they began to expand rapidly about 1950, Roemer said. In that year, the Saskatoon plan began to seek voluntary enrollments in rural communities, and by 1955, it had enrolled at least 75 percent of the population in each of 18 towns and villages and 58 rural municipalities (75 percent was the minimum to qualify for inclusion in the plan).

Membership charges are much higher than the taxes under the municipal doctor plans, but the voluntary plans have the advantage of free choice of almost any general practitioner, including those under municipal contract, and any specialist in the Province, he pointed out. Prosperity, improvement in roads, increase in the number of automobiles, and popular writing about modern medicine, he indicated, have helped to provide a favorable climate in the rural areas for the growth of the voluntary plans.

In 1955, Roemer stated, the average annual cost of the Saskatoon

community plans was \$18.50 per capita, with a usual family charge of \$72. Also, to reduce expenditures, it has been necessary to introduce restrictions—for example, a \$600 limit on services to an individual in any one year for any one illness; a \$25-a-year limit on diagnostic X-ray and laboratory examinations; no care for allergic or psychiatric conditions. Another weakness, Roemer said, is the fact that 25 percent of the population is not covered and that these largely represent low-income families in special need of medical care.

Regional Plans

Another possible solution to the difficulties in providing rural medical care was recognized in 1945, when a prepaid medical care plan was organized in the Swift Current public health region, Roemer stated. All 36 physicians in the area participate in the plan, so there is a free choice of many physicians, and all 50,000 residents of the region are entitled to services. It has been possible, he reported, to provide "quite comprehensive medical services at an annual cost of about \$14 per capita."

The quantity of medical services is considerably higher than under the municipal schemes, and the quality is doubtless as good as under the voluntary schemes, he maintained. Another good feature is the encouragement of preventive services.

However, Roemer does not consider the regional plan completely satisfactory. He noted, for one thing, that the people still must rely heavily on general practitioners even for relatively complex procedures. Only on a provincewide basis could the people have access to all medical skills, he said.

Roemer observed that from the use of all 3 plans it could be said that in Saskatchewan's experience with prepaid care hospital admissions are increased rather than reduced. In rural areas without prepayment plans, the admission rate was 197 per 1,000 in 1954 as compared to the 260 admissions per 1,000 persons per year in the Swift Current plan region.

"Whatever benefits may derive from early diagnosis under prepayment, the very access to a doctor evidently results in case finding and hospital therapy to an extent which causes overall increases in hospital utilization," he remarked. He estimates that, in its varied forms, prepayment now covers 45 percent of Saskatchewan's population.

Efforts to launch new regional schemes within the last year have been unsuccessful. Plebiscites on new taxes to support the plans decided against them, he reported. Roemer believes, however, that negotiations with the medical profession, which has recently come forward with a new prepayment plan, should ultimately result in a mutually agreeable regional plan.

But still other steps are necessary for improved rural medicine, Roemer declared. "The challenge is to provide a general medical practitioner close to the people, yet working in a framework which would permit him—without financial loss—to refer cases readily to a specialist's care."

To achieve this objective, Roemer suggested that rural general practitioners might be attached to medical groups, with a group clinic located in a large town. The village physicians could refer difficult cases to the clinic, and major surgery could be done in district hospitals, he said. The village physicians would share in the income earned by the group as a whole.

Saskatchewan Shares Prepaid Plan Data

How statistical data derived from prepaid hospital and medical care programs are used for knitting Saskatchewan's health services into a comprehensive and balanced unit was described by Murray S. Acker, M.D., D.P.H., and L. G. Williams, M.A., of the Saskatchewan Department of Public Health, Regina, Canada.

Public health and medical or hospital care agencies are continually

designing records and collecting data, and often no one seems to know how all of this interesting information can be put to use, they said. All the data may not be relevant to the immediate tasks of an agency. But many times they could be of inestimable practical value to another agency operating in a different sphere of health activity if there were some mechanism for sharing the information, they explained.

Saskatchewan, they acknowledged, has the mechanism and a more than customary motivation for achieving coordination of services. Although diverse in coverage, benefits, and maturation, the existing provincial, regional, and local programs are predominantly tax-supported and publicly controlled, and they are directly or indirectly supervised by the provincial health department.

In their advance along parallel fronts toward a universal, comprehensive service, coordination is mandatory to avoid serious contradictions and inequities, they said.

Contributing data with the widest application, they reported, are the provincewide hospital care insurance plan with eligibility for benefits contingent upon prepayment of a tax premium; the Swift Current region-wide prepaid medical care program covering every resident with a wide range of benefits on a tax-supported basis; and the provincewide public assistance program providing a virtually complete range of health benefits to the indigent and near indigent.

These data are timely and reasonably accurate, they said. Moreover they are referable to the total population in the Province, or in a geographic region, or within a specific socioeconomic group.

Acker and Williams pointed out that within Saskatchewan's organizational framework any parallel agency, inside or outside the health department, has ready access to the statistical data of the operating prepayment programs, and thus the data are of potential value beyond their requirement for the immediate

administrative functions of the prepayment agency.

Initial steps have been taken to use the data for planning specific public health projects, they said. Decisions requiring the extension of medical care benefits have been guided by precise measures of morbidity.

Analyses of hospital care data have been valuable in formulating indexes of bed need in specific areas and in stimulating higher standards of care. The data have supplied material for epidemiological studies and for public and professional education.

In Health Project

Illustrating the use of prepayment plan data in deciding policy and planning a public health project was an account of the organization of a regional program for rheumatic fever prophylaxis.

Hospital caseload and cost data demonstrated that a successful preventive program, using daily oral penicillin at an average annual cost of less than \$40 per capita, would in time realize substantial savings in hospital care costs in a public program. The 852 hospital discharges for rheumatic fever and the 385 discharges for chronic rheumatic heart disease in the typical year of 1952 accounted for 25,585 patient-days of hospital care at a cost of almost \$210,000. Medical care costs added a further estimated \$52,000.

After the program started, the hospital records solved the problem of case finding in the region. Lists of the 106 regional patients hospitalized with rheumatic fever over a 5-year period, plus relevant data such as age, residence, attending physician, and hospital, gave the officer immediate information on the majority of potential candidates for prophylaxis.

Another example illustrated how universal insurance plan data can fill in the gaps and delays inherent in compulsory reporting of notifiable diseases. The Swift Current medical care plan yielded early information on primary cases of infectious hepatitis during an upswing of incidence in the region. The knowl-

edge, gained from the daily medical account forms of the practicing physicians, facilitated the widespread administration of gamma globulin in the prevention of secondary cases.

Use Pattern

In the hospital program itself, the operations data have proved valuable adjuncts in studying such factors as variations in the patterns of use, they reported.

They gave as one example the higher rate of use in rural than in urban areas revealed by the service statistics. Characteristics of the areas of highest use, a study found, were greater rurality, low population density, larger families, lower land values, and greater distances from large cities.

Inadequate resources for home care and a smaller supply of physicians, it was concluded, figured in the high use rate.

In the rural "high" areas patients with influenza, pneumonia, and bronchitis were admitted 4 to 6 times as frequently as similar patients in the urban low areas of use. Though admitted less frequently, the urban patients with respiratory illnesses had longer periods of stay. In other words, they said, less seriously ill cases in the larger urban centers were much more likely to be cared for at home.

By these analyses, they said, high utilization is more intelligently understood as a combined product of social, geographic, and professional conditions than the result of personal whim on the part of the patient and his doctor.

Indigent Medical Care Plan Operated by Physicians

The key to the success of the Topeka plan for providing medical care for the indigent is its operation by local members of the medical profession, in the opinion of Glen C. James, director, Shawnee County (Kansas) Social Welfare Department.

Now in its 13th year, the plan has received nationwide attention and the "seal of approval" of the American Medical Association, James stated. He outlined the plan's main features as follows:

By monthly contract, the public welfare board employs the county medical society to obtain complete medical services, hospital care, and drugs for patients referred from the county's public welfare rolls. The board agrees to pay the society a lump sum, based on a fixed amount for each person sharing in the benefits of a public assistance grant. (Until July 1953, the payment was on a family unit basis.) As an agent of the welfare board, the society then asks all its member physicians, 102 in number, to give professional services to referred welfare recipients.

The plan is primarily clinical in nature, with 17 well-equipped clinics staffed by physicians of the society on a rotation basis. However, both day and night house calls are made, and diagnosis and treatment may be given in a physician's office at the physician's request. Hospital care is authorized by the attending physician and paid for by the society. Prescribed drugs are dispensed at the medical society drug store during the day, or, if dispensed elsewhere after clinic hours, they are paid for by the society.

The physicians are paid by the society on a unit of work basis, according to a set schedule: An office or clinic visit is 1 unit; a day home visit, 3 units; a night call, 5 units; an obstetrical case, 20 units; and major surgery, 35 units. The cash value of the unit varies, since the funds remaining each month after all outstanding bills have been paid are prorated among the physicians on the basis of the number of units of work done.

The welfare clinics are staffed with nurses and clerical personnel employed by the local public health department, which is located in the same building. The clinics and the

health department also use the same laboratories.

A Minimum of Problems

Problems in connection with this medical care program are held to a minimum, according to the welfare director, by the extensive use of committees that hear complaints and work out necessary changes: a committee on hospitalization, a consultation committee, a clinic committee, a drug committee, a complaint committee, and a finance committee.

Among the problems he mentioned is "the often legitimate gripe of the physicians that persons demand excessive services just because there is no extra charge for extra services." Another is the fear on the part of the patients that public medical care will be inferior to private medical care.

To help make the plan function smoothly, there are a few restrictions, James said. For example, the attending physician may not hospitalize a patient for longer than 2 weeks without the consent of the hospitalization committee; new drugs cannot be used until the drug committee adds them to the available list.

Recently, the medical society and the welfare board agreed to permit the physicians to charge patients \$1 for each house or office call, the charges limited to two a month, James reported. The practice was abandoned after 3 months' trial on the suggestion of the physicians, who found that it was "both unpopular and unprofitable."

Samples Union Opinion Of Group Care Plan

A study on how the patient-members felt about the Labor Health Institute of St. Louis, Mo., a prepaid union group medical and dental plan, was reported by Nathan Simon, M.D., and Sanford Rabushka, M.D., interns at Jewish Hospital in St. Louis.

The institute is one of the oldest and most successful comprehensive, prepayment group practice plans, they said. Founded in 1945 by what is now the Warehouse and Distribution Workers' Union, AFL, the institute provides comprehensive medical and dental care to 15,000 union members and their families, a low-income group of semiskilled and unskilled warehouse workers, they reported.

The institute's complete dental program makes it unique among plans of its type in the United States, they declared.

Financing is by employer contributions of 5 percent of the gross payroll in most of the firms covered and provides protection for the union member, spouse, and all children under 18, they reported. In a few shops the employer's contribution is 3½ percent of gross payroll and covers only the union member, they added.

Findings

On the basis of a sample of 199 of 15,000 members they found that:

Sixty-five percent expressed unqualified approval, 21 percent were satisfied but had some criticism, 7 percent had no opinion, and 7 percent expressed marked dislike of the plan.

The dislike was correlated with dissatisfaction with the patient-doctor relationship. It appeared that people who disliked the plan entered it with preconceived ideas which precluded their acceptance of the plan.

Members who used the institute found the quality of professional care satisfactory and were able to establish stable doctor-patient relationships the same as before joining the plan.

The institute provided about 80 percent of the total professional services of the sample for the year studied. The most frequent reason for using outside services was a strong attachment to a physician or dentist not on the staff of the institute.

Service Statistics . . .

Sound Service Statistics Measure Achievement

Sound service statistics are essential in maintaining or redesigning the original plan of the public health program as it progresses, stated Evelyn Flook, chief, Public Health Practice Studies, Division of General Health Services, Public Health Service.

The Working Group on Service Statistics of the Public Health Conference on Records and Statistics, the National Conference on Evaluation in Public Health, and the Committee on School Health Service Statistics of the American Public Health Association are promoting the concept of sound service statistics for program management. The working group has defined service statistics as meaningful numerical measurements of services rendered to individuals and to the community through public health programs.

Statistics which focus attention on numbers and kinds of persons served, types and amount of service rendered, and what happened as a result of the service are not to be confused with traditional activity counts, Flook said. True measurements of accomplishment cannot be arrived at by counting units of service alone, she said.

Sound service statistics can provide perspective for judging success or failure in achieving stated objectives or in making progress toward them, she continued, adding that service statistics can serve as the gauge for distributing or redistributing resources and for determining whether and when program operations should be realigned.

Useful Data

Flook said that the factor of interrelatedness was more important than any other in the development of sound service statistics. Case rec-

ords of individuals served by the health department are an excellent source of data, she noted. She continued:

"The units of measurement which apply to service rendered must be related to such baseline data as population, by age groups; morbidity, natality, and mortality; the health needs of special groups—not as seen by the public health worker alone but as also seen by the people; health facilities, services, and personnel available under public, voluntary, and private auspices; housing, sanitation, nutritional and general economic status of the community; and information reflecting expenditures."

In addition to being related to baseline data in establishing quantitative relationships between the service rendered and the health problems involved, service statistics, to be most useful, should:

- Be designed to serve a specific purpose, such as help define a health problem, help measure extent of service, help measure progress in relation to the problem, help furnish a basis for future planning.
- Be developed in accordance with clearly defined program objectives.
- Reflect service to people—not

merely enumerate volume of activity of the health department staff.

- Be sufficiently limited in scope and volume to justify the time, effort, and expense involved in production.

Preparation of recurrent statistical reports can be simplified by making special limited studies in place of routine collection of complex mass data, Flook added. Short-term studies, often based on a sample of the total and aimed at answering specific questions, are economical. Frequently, they pinpoint the particular problem at issue, she said. Well-controlled epidemiological studies, with appropriate appraisal of differences in effect, are classic examples of the use of service statistics which show the population affected and that unaffected by a particular problem, she remarked.

Flook then outlined how useful statistics might shape up for evaluation of programs. For a single segment of a school health program, they might include:

- The school population covered.
- Number of children examined.
- Number of children not examined who should have been.
- Number of children with health needs.
- Number of defects or abnormalities for which further attention is indicated.
- Correlation of the abnormalities found with those corrected.

Planning and Management . . .

Administrative Management Concept Is Supported

If health officers availed themselves of modern administrative practices, they could devote more time to medical matters and less to administrative duties, stated Murray L. Nathan, LL.B., director, of-

fice of planning and procedures, and Herman E. Hilleboe, M.D., M.P.H., commissioner of health, New York State Department of Health, Albany.

Personnel and fiscal management have developed into specialties for which professional public health officers have not been trained, they said.

Nathan and Hilleboe defined administrative management as overall administration rather than any specific phase of management or administration. Its goal in public health, they said, is to create an environment in which many persons from different disciplines may aid health officers to reach a common objective.

"Administrative management is not a catchall for miscellaneous clerical duties but is an activity involving high skills in management and operations control," they stated. "To handle skillfully a complex administrative problem is as significant to the progress of public health as a well-executed epidemiological investigation of an outbreak of disease."

Approach to Problems

One of the features of administrative management is its systematic and analytical approach to problems, Nathan and Hilleboe continued. Public health activities and objectives must be analyzed and evaluated to determine how well they meet the needs for which they were established and whether each activity is an appropriate responsibility of government or of private groups or individuals, they stated. Health workers must define priorities among their activities, point out special areas for needed research, suggest, develop, and test new programs, recommend for adoption only those which have had successful tests on selected populations, and be alert to the appropriateness of a particular activity as a government responsibility, they said.

In health department organizations, such nonmedical titles as "deputy commissioner, administrative services," "personnel administrator," and "director of planning and procedures," indicate that, with the delegation of important administrative duties to persons especially trained and experienced, "administrative management has come of age," they pointed out.

Training Personnel

When the concept of administrative management has been accepted

by the health department, the health officer has the practical problem of acquiring trained personnel, Nathan and Hilleboe said.

Some schools of public health now offer courses in nonmedical administration leading to a master's or a bachelor's degree in public health. A school of public health is an ideal place to train these people, they said, and joint training of medical and nonmedical public health personnel should lead to joint working arrangements in the field.

In conclusion Nathan and Hilleboe stated that a continuing program of education, training, and research must be carried on in health departments to keep personnel currently informed of changes in administrative management and public health, to develop new techniques, and to put these techniques into practice quickly. Also, administrative management personnel themselves must take advantage of every academic aid offered.

Philadelphia Simplifies Sanitation Records

A new system for recording sanitation inspections, using a single record form, is employed in Philadelphia's milk and food sanitation program.

Morris Shiffman, D.V.M., chief, milk and food section, and Paul W. Purdom, director, division of air pollution control and environmental sanitation, Philadelphia Department of Public Health, reported that the system was field tested for a year and proved to be successful in operations research.

The new record system fits in with the new inspection system which was adopted several years ago when the Philadelphia Department of Public Health reorganized the division of air pollution control and environmental sanitation and changed from a specialized to a generalized type of inspection, Shiffman and Purdom stated. Under the new system, the sanitarian is responsible for all

types of inspection of milk and food establishments as well as for other phases of the environmental sanitation program.

They said that the concept of sanitation unit operations and processes opens up new opportunities for the simplification of sanitation record forms. Multiple forms may be replaced by basic single forms to include any group of related environmental sanitation activities.

Single Record Forms

All data are now recorded on a single sanitation form and are processed by the IBM punchcard method, Shiffman and Purdom stated. The single form serves three purposes: It provides the inspected establishment with a positive, clear indication of what is required to meet standards and improve operations; it gives the administrator the information that will aid him in program planning and evaluation; and it provides legal records.

The single record form does away with the need for a separate form for each type of milk and food establishment, Shiffman and Purdom said. In addition to the general heading, there are two separate information areas on the form. One consists of ruled lines and columns where the sanitarian lists his recommendations to the establishment; the other is a check sheet intended solely for departmental information and data for the IBM punchcard records.

The sanitation items included in the check sheet are selected to cover those basic operations and processes which are essentially common to food and milk establishments and which give useful information for analysis, they said. The methodology for the choice of items is analogous to the concept of unit operations and unit processes in chemical engineering and food technology. Extraneous detail has been avoided so that the analytical system does not bog down from the sheer weight of detail.

Uses of Data

Some of the data currently derived from the record system include an enumeration of specified sanitation defects found on inspections and information as to whether these defects have or have not been corrected, Shiffman and Purdom said. In this way, the degree of compliance with any recommendation can be measured. Provision is made for analysis of survey items and for field research projects.

In conclusion, they stated that the completed analyses permit a measure of the effectiveness of personnel and an evaluation of the methods and activities of the organization. The problem areas may be pinpointed and success or failure in correcting any sanitary defect may be measured.

Executive Must Clarify Management Role

A definition for "management personnel development" is to "get people to do more than they themselves think they can do," according to Virgil K. Rowland, personnel assistant to the vice president and secretary, Detroit Edison Co., Detroit, Mich.

Managers frequently do not know what is expected of them or what they should expect of subordinate management personnel because the department head has not discussed with them the responsibilities of the job or the standards of job performance, Rowland stated.

Job descriptions, performance standards, and individual evaluation of job performance provide a basis for improving managerial performance, he said.

Job Descriptions

A job description should be more than a list of the manager's specific duties; it should include a statement that management functions include the broader phases of management, such as responsibility for plan-

ning, controlling and executing; being a leader of subordinates; and directing the work of others.

Rowland said that too often job descriptions are merely statements that the job of subordinates, including managers, is to get the work out. The manager's responsibility is to direct others, not to get the work out himself, he emphasized. Companies which define a manager's job with a description of the duties and responsibilities of subordinate managers are in the minority, he added.

Performance Standards

Department heads are apt to feel that managers should know what their responsibilities are and how to carry them out. "We feel that we are insulting their intelligence if we try to tell them how to be good managers," Rowland stated, but it is the responsibility of the executive and not the personnel director, the industrial relations man, or a staff member, to talk with the manager about his job and the standards of performance he is expected to meet.

Rowland cited the experience of the president of a company with his sales manager. The man was an excellent salesman and the company's sales were the envy of its competitors. The sales manager had been helpful to the president in many ways and had set high quotas for sales. But, said the president, "I still had the feeling that my general sales manager was not part of my team."

Discussion disclosed that throughout a close association of 12 years each had suspected that the other was unhappy in the relationship, and that the sales manager was about to go to another company. Furthermore, the president found that the sales manager did not know what his job was. "I couldn't censure him for that," the president said, "because I realized that I hadn't discussed it with him."

Together, they determined the major segments of the sales manager's job and a satisfactory level of performance, as well as his respon-

sibility for planning for future growth. A few days later, the manager called a meeting of his regional sales managers, and a week later they met and set standards for their own jobs. That, said Rowland, "is management personnel development in action."

Evaluation of Job Performance

To be helpful to employees and effectively to evaluate their job performance, management personnel must discuss with each individual the evaluation of his job. This is where management often fails, Rowland said. "We do everything but talk to the individual about his evaluation. And the reason we don't do it is because our boss, the next man above us, has not insisted that we do it. We do what the boss inspects, not what he expects," Rowland pointed out.

"The boss must know in what areas his employee is doing a good job and in what areas he needs to improve. . . . Individual evaluation of managerial performance is becoming an accepted philosophy in many companies today," and it is "a responsibility that cannot be delegated," he emphasized.

In conclusion, Rowland stated that any one of three techniques—statement of responsibility and authority, determination of performance, and evaluation and discussion of his performance with each employee—will improve managerial performance. When all three techniques are used and interrelated, the results are compounded and the improvement begins to be apparent in the profit and loss statement. Companies using these techniques can pay their employees more and can reduce their production costs, he said.

Michigan Broadens Use Of Marginal Punchcard

An adaptation of the marginal punchcard system of recording environmental health activities and

programs has extended the use of this method and has made possible a more thorough and intensive administrative review of departmental functions, according to Vinson R. Oviatt, B.S.C.E., M.P.H., engineering consultant, hospital unit, Michigan Department of Health, Lansing.

Almost all record systems record historical facts, Oviatt stated, but assembling information requested by other agencies usually is expensive to the health department in terms of personnel time. Furthermore, he said, few record systems provide information needed to plan workloads within units and departments, to justify budget request expenditures, and to plan programs, or provide bases of communication to the public, to superiors, or between sections or divisions of a working unit.

After studying the relative merits of mechanical and punchcard systems, three Michigan public health workers selected the marginal punchcard system as the simpler and more economical. The only equipment needed is a hand punch for notching the cards, an alinement block, and a sorting needle, Oviatt said, although offices having a large number of cards to count and sort may purchase other equipment which will speed up summarization of the data.

The system has a number of advantages for reporting and recording sanitation activities and services, Oviatt stated. These are: rapid collection of information; summarization of records and data without transcription; only one form necessary; variation in use with the same basic forms; economy in cost of equipment and forms and in personnel time; relatively accurate and extensive use of quantitative data; compatibility of information among health departments; and logical balance between field and departmental use of records.

Punchcards and Forms

The marginal punchcard and the inspection form are essentially identical, with two exceptions, Oviatt

said. The coding information on the card does not appear on the inspection form, and a condensed check list of sanitation items usually inspected at all types of establishments has been added to the bottom of the punchcard. At the end of the check list, several items have been left blank for the use of individual sanitarians in recording selected data. Several unallocated code sections have also been left for coding special studies or data.

Space has been left on the inspection sheet for the sanitarian's remarks to the operator of the establishment and, at the bottom of the sheet, for signatures of the inspector and the operator.

Michigan uses a multiple-purpose form, Oviatt said, that can be used not only for reporting sanitary inspections of all types of establishments—food, milk plants and producer farms, slaughterhouses, and sewage treatment plants—but for coding data on all other programs of the health department and for recording complaints. The heading of the form has space for the date, names of establishment and operator, address, establishment number, license number, location, and type of establishment, and for the name, address, and telephone number of the complainant. Individual check lists for the different types of establishments are carried in the sanitarian's notebook.

Coding and Filing

The American Public Health Association code for reporting sanitation activities and programs is the only code specified for general use with the marginal punchcard system, Oviatt stated, and in Michigan, this master code has been expanded to fit sanitation practices in that State.

Each health unit records the data in the same way, although each one must work out its own code for geographic location and identifying numbers of sanitarian and establishment.

Each sanitarian notches the

punchcard when he fills out the inspection form. This not only saves office time but insures accuracy in coding because if coding is done by clerical personnel, some misinterpretations of the sanitarian's findings are bound to occur, Oviatt emphasized.

Cards may be filed by program, by sanitarian, by area, or by any other method that fits the needs of the health department, he said, and they may be summarized as often as necessary. Most health departments summarize data monthly.

Other Uses

Punchcards have been useful in recording office activities, such as time spent on a special program or on program planning, itemizing correspondence, or recording information, conferences, and staff meetings, Oviatt stated.

In Michigan, monthly reports of programs, by activities, enable the State health department to evaluate health programs with a minimum of effort. Among the various uses made by individual health units of the data obtained by the marginal punchcard method are reporting of services to political subdivisions, providing summaries of activities to controlling governmental bodies, time and cost analyses, comparison of services to different areas, analysis of work of individual sanitarians, and evaluating and planning of programs.

The system can be used to evaluate programs, establishments, or geographic areas over a period of time by comparisons of types and numbers of activities, number of deficient items, and approval status. However, sanitarians and statisticians in Michigan are exploring other adaptations of this method in measuring the quality of an activity or program, Oviatt stated.

In conclusion, he reported that the success of field trials of the marginal punchcard system has resulted in its continuation in the trial areas and in its adoption of health units outside these areas.

Cooperation of Agencies Still a Major Goal

Cooperation between health and welfare agencies can be achieved; it can produce improvement in services to people; but it is still not often practiced.

This evaluation was the conclusion of Jonas N. Muller, M.D., M.P.H., staff director of the Subcommittee on Medical Care, American Public Health Association, and Pearl Bierman, M.A., medical care consultant, American Public Welfare Association. It is based on visits with State and local health and welfare department personnel in eight States and current reports in the literature.

Many different forms and degrees of cooperation are found, they specified. However, most cooperative efforts are somewhat remote from the recipients of services, and few are vigorously directed at health goals. Cooperation is rarely explicitly defined in policy terms, they added.

Not noncooperation, they explained, but simply no relationship at all on the administrative level, is the usual situation. Many health officers, however, informed Muller and Bierman that they avoided making any special provisions for health services to the indigent for fear the health department might be labeled as an agency for this group.

Areas of Cooperation

The major area of well-defined cooperative effort among State agencies centers around boarding homes and such institutions. They are particularly cooperative on licensing programs, Muller and Bierman noted. Such efforts range from contractual agreements for the participation of several agencies to informal but regular visits by field personnel of the licensing agency to other agencies. In California, for example, a tripartite agreement concerning standards and licensure responsibilities for sheltered care facilities for older people provides for consultation services from the State

departments of public health, social welfare, and mental hygiene.

For the most part, they stated, the cooperative efforts in this area are effective. But their potential for improvement of institutional services has barely been tested. Nor have they been sufficient to bring about consideration of other areas of mutual concern.

Muller and Bierman pointed to the lack of application of preventive services through joint effort as the most glaring gap. One welfare agency head even suggested that any notification to welfare clients of the availability of preventive services would constitute coercion and that it was therefore not an appropriate activity, they specified.

In the field of chronic diseases and adult rehabilitation, the situation seems to be little better, although possible pointers to future patterns exist in a few States. In cancer control, for example, State welfare departments have some responsibility in at least eight States.

At the local level, the greatest evidence of cooperation is in the area of direct services, according to Muller and Bierman. Usually, the cooperation is among the workers, not the agencies, and is informal and unplanned.

Five Basic Goals

If the preventive approach to health and welfare problems is to be followed effectively and economically, cooperation between health and welfare agencies must be greatly increased, they declared. They said that the following basic goals are still to be achieved:

1. The application of the normal program of the health department to the welfare population through active cooperation with welfare agencies.

2. The development of appropriate health promotion and disease prevention activities in the welfare program itself.

3. Recognition of the opportunities for improved health and welfare services inherent in areas of overlapping responsibilities, such as the

licensing of institutions, rehabilitation, and certain aspects of tuberculosis control.

4. An increased awareness of the social and economic needs of persons coming to the attention of the health department and a clear understanding of the responsibilities and the potential activities of the welfare agency in support of people with such needs; and an understanding of health needs and of the resources of the health department by the welfare department.

5. The development of the necessary policy and procedures to achieve economical and efficient services, without duplication, when several agencies are concerned.

Annual Fleet Purchase Pays in Maryland

Mileage costs for transporting Maryland State Health Department personnel have been reduced to 3.1 cents per mile—a saving of 3 cents per mile over former years—by the use of an annual fleet turnover plan.

Clemens W. Gaines, B.S., chief of the department's bureau of management, described the plan and discussed how the reductions in costs came about.

Formerly, Maryland bought 285 automobiles, 230 of which were assigned to rural areas. These cars serving 680 employees were driven an average of 9,500 miles annually and were replaced in 6 years or at 60,000 miles, whichever came first. The fleet was managed and serviced by an 8-man staff in a central garage.

Under the present plan, new cars are purchased on a bid basis at prices reflecting wholesale rates. They are resold at the end of the year to highest bidders, usually at prices reflecting the one-third depreciation from retail list prices. Thus, Gaines explained, the State has the opportunity to purchase a new car with little more than the proceeds realized from the sale of an old one.

The figures for 1955 show that the department was able to acquire its new cars at a cost of about \$26.32 per car, a figure which includes \$12.70 for the administrative costs incurred in selling the old.

For the same year, the itemized mileage costs in cents were as shown in the table below.

Gaines pointed to the following features in the plan which have resulted in reductions in overhead and operating costs.

- Only regular grades of gas and the cheapest separately packaged and sealed oil are purchased under 6-month contracts with local service stations.

- Garaging of cars has been eliminated.

- There is no depreciation from injury to the finish, caused by removal of State or official seals from the door; instead, cars use a metal tag reading "Official Use—State of Maryland."

- The purchase of seat covers has been discontinued.

- Instead of buying black cars and the cheapest model of one manufacturer, the State buys from the manufacturer submitting the lowest price for cars which have good resale values.

- Since the cars are new, there are few repairs; thus, the central garage is scheduled to be vacated this year, and only one person will be retained to manage assignment and repairs.

- It is planned to assess nominal charges on personnel using the cars for commuting purposes.

Since about 165,000 used cars are sold each year in Maryland, the size of the deal, 286 cars, does not seriously affect the used car market, Gaines said.

The plan, which saved \$85,000 out of \$153,000 in 1955, makes it possible to use more of the tax dollar for di-

rect health services by clinicians, nurses, statisticians, and others, he concluded.

Profile of Health Worker Drawn From Yale Project

The average public health worker enters the field of public health after 7 years' experience in other fields. His entry into public health is most often the result of chance, personal contacts, or the inherent attraction of the work. In addition to his other experience, the average worker has had 10 years' experience in public health.

This picture of the public health worker is based on findings of the Yale Public Health Personnel Research Project, which were reported in summary form by Edward M. Cohart, M.D., deputy director of health, New York City, and Ira V. Hiscock, Sc.D., chairman of the department of public health, Yale University School of Medicine. (Several detailed reports of the study have been published in this journal.)

Through interviews, observation, and time studies, the Yale project obtained information on education, work experience, satisfactions and dissatisfactions, and activities of public health workers. A total of 1,129 personnel in selected State and local health departments in 4 States were studied, although not all were included in each phase of the project, according to the Cohart and Hiscock report.

Their summary, they noted, provides "good approximations of the facts, rather than scientifically exact descriptions," because of State-local differences and the way in which the sample of health departments was selected. Other findings, as reported in their summary, are given below.

Sixty percent of the public health workers possess bachelor degrees. About 27 percent hold graduate degrees, but only a minority of these have degrees in public health. Education in the natural sciences is the

rule; education in the social sciences is uncommon.

Most public health workers are happy to be in public health, but 1 in 7 feels that he would like to work elsewhere. More specifically, unsatisfactory conditions of work and low salaries are the most frequent reasons for discontent. Relations with fellow workers are the greatest source of satisfaction.

Distribution of Working Time

Distributions of working time to public health programs and to specific functional categories of activity were each studied in one State, Cohart and Hiscock stated. On these phases of the Yale project, they reported the following:

In local health departments, between 33 and 50 percent of all working time is devoted to maternal and child health; 25 percent to environmental sanitation; approximately 10 percent, respectively, to communicable disease, tuberculosis, and venereal disease; and about 4 or 5 percent, to chronic disease, mental health, industrial hygiene, and civil defense, combined. There is some overlapping of these divisions.

In the State health department, venereal disease receives major emphasis, closely followed by maternal and child health. Orthodox sanitation programs account for 10 to 15 percent of the time, but another 20 percent is devoted to industrial hygiene. Tuberculosis and communicable disease each takes about 10 percent of the time. And the remaining 10 percent is devoted to chronic diseases, mental health, and civil defense.

About one-third of the time of health department personnel is devoted to giving direct services; one-third, to administration and community activities; and one-third, to supporting activities.

Cohart and Hiscock felt that the findings of the Yale project "should serve as useful preliminary observations," even though future studies on a broader base may alter the percentages. "The findings are to be looked upon not merely as a descrip-

tion of existing conditions, but, even more, as the necessary information for an assessment and evaluation of current public health practices, especially in relation to factors of administration and personnel," they said.

Record and Evaluate In One Technique

New Jersey has a carefully designed technique for recording and adopting public health programs which its proponents maintain can minimize subsequent difficulties in program operations and simultaneously serve as a potent factor in achieving critical evaluation.

The new technique was described by Daniel Bergsma, M.D., M.P.H., and Lawrence M. Friedrich, M.C.E., M.S.P.H.E., commissioner and assistant to the commissioner, respectively, New Jersey State Department of Health.

The method of recording is not an end in itself, they stated, but an orderly administrative process to record and evaluate a plan of procedure for each specific, stated goal designed to prevent disease or to enhance the health of the community.

When clearly stated, they declared, adopted objectives constitute a summary of the need or problem, a reflection of background philosophy, a declaration of intent, and the indicated policy. The adopted activities indicate scope; may further clarify needs; usually imply personnel, time, space, coordination, and integration; and always imply procedure and policy.

Four Basic Parts

They explained that plans recorded by this technique contain four essential parts:

Part I contains a statement of specific public health needs. This expresses the lack of anything requisite, or the presence of anything harmful, to optimal health, plus the concise enumeration of related problems. Pertinent statistical data are

included. The purposes of part I are to justify the proposed plan, to define the situation, and to provide a baseline for measuring progress.

Part II states the objectives of the particular program, the specific activities for each objective, designates responsibility for each activity, and provides the first broad guidelines on cost.

Part III consists of general guidance for the program and explicit detailed procedures for each activity. The third part is designed to provide all factual and procedural data necessary for an employee with minimum training to conduct each of his activities correctly and is intended to leave only carelessness or poor judgment as reasons for failure to act correctly.

Part IV contains the predetermined yardstick or indexes to measure progress in terms of the program as a unit or of the objectives. This consists of a series of built-in evaluation indexes which emphasize accomplishment and quality.

Three facts stimulate optimal performance and critical self-appraisal of any program writer when the method is used, they commented. Every item of every program has its assigned place on the prescribed format and can readily be cross-checked by a reviewer. Colleagues and superiors of a program chief will constructively, but critically, review his program and determine by group judgment whether or not it is consistent, adequate, and practical; everyone involved is free to, and is urged to, send suggestions for improvements to the department head.

Most programs were rewritten at least once or twice, and some three or more times before unanimous or majority adoption, they said. This provided a significant training period for the personnel recording a program, strengthened the realism and logic of the approach, increased efficiency of performance, imparted a sense of accomplishment, improved morale, and heightened appreciation of departmental problems and goals.

The selection of students is another responsibility that the health agencies share with the schools of public health, according to Vaughan and Getting. Basic to securing good personnel is, of course, the recruitment of people of integrity, intelligence, morality, and maturity. In addition, if the teaching of public health is to be improved, the students must be leaders in their chosen disciplines, that is, in medicine, nursing, health education, engineering, or nutrition, for example.

Vaughan and Getting also felt that ideally every student should have some public health experience prior to matriculation. This experience should be planned; it should be obtained under supervision; it should be as broad as possible; and it should lead to increasing responsibilities, they specified.

One way of assuring the schools of qualified students, they said, is through careful selection of candidates for fellowships by the agencies that have fellowship programs. Unfortunately, there are not enough fellowships available, they added, urging that all State and large local health agencies, both official and voluntary, plan specific training programs, including intramural postgraduate education.

Theory Into Practice

"Every course of instruction in a school of public health leading to a graduate degree should be so designed that the recipient will be prepared for the practical application of the theory and dogma which he has encountered during the school year," Vaughan and Getting emphasized. By this, they said they meant that opportunities to relate academic instruction to field practice must be provided as the program of instruction progresses, not before nor after the course of instruction. Too frequently, they pointed out, academic exercises are drawn from the files on situations of yesteryears rather than from situations existing today. They recommended a blending of history and everyday problems in the course of instruction.

Professional Education, Training . . .

Agencies Can Aid Schools In Preparing Careers

Health officers must aid the faculties of schools of public health in preparing personnel for health agencies by indicating what they expect the graduates to obtain during the period of instruction, stated Henry F. Vaughan, Dr.P.H., and Vlado A. Getting, M.D., who presented the schools' views on how the teaching of public health can be improved.

Drs. Vaughan and Getting are, respectively, dean and professor of public health practice, University of Michigan School of Public Health.

As personnel, duties, and responsibilities in health agencies change,

so courses of instruction must be altered to meet these needs, they said. Whenever possible, the schools should anticipate the future needs of health agencies and prepare students for future duties and responsibilities.

At present, they said, because of the general evolution taking place in the character and nature of health services, the schools must prepare students for any eventuality, be it medical care administration or home care of the chronically ill. Until the health officers can give more definition to the future horizons of health programs, the schools would be derelict in their duty should they restrict their teaching program to a narrow approach to health matters, they added.

Along the same line, they mentioned the necessity for the faculty's keeping up to date on public health practice. Keeping "one foot in the field through active association with progressive health agencies" is an advantage for the teacher that cannot be overemphasized, they said.

Also of paramount importance is the selection of the faculty, Vaughan and Getting noted. They described the ideal faculty member as "a professional person with a wide variety of experiences." Rarely should a person be selected who has not had continuing experience in the practice of public health, preferably in a local health department as well as in a State agency, they said.

Health Department's View Of Teaching Public Health

Seven questions related to the problem of improving the teaching of public health were raised by Franklyn B. Amos, M.D., and Herman E. Hilleboe, M.D., director of the office of professional training and commissioner of health, respectively, of the New York State Department of Health, Albany.

The gist of their comments on each question reflecting the health department viewpoint follows:

Objectives of the graduate school of public health. An analysis of the backgrounds of medical M.P.H. candidates in all graduate schools in 1951-52, as reported by the Committee on Professional Education, reveals that there were 98 foreign students, 86 native students with prior public health experience, and 33 native students without such prior experience. Perhaps those schools with a preponderance of foreign students aim chiefly to provide training for foreign public health; those which accept students without previous experience, to provide initial preparation for the job.

School admission policies. Relaxation of the 3-year experiential requirements for most candidates might solve some recruitment prob-

lems, but necessary professional and personal characteristics should be part of the admission criteria of all schools. Intellectual capacity and professional knowledge should be such as to indicate ability to complete work at the master's degree level.

Curriculum policies. Part of the problem in setting educational goals is the lack of agreement on the area of knowledge to be included in public health. The number of electives offered at the schools varies from 15 to 127. More courses in the social sciences and administrative sciences are needed by many schools.

Teaching techniques. Prominent researchers do not always have teaching abilities. Responsibility for assuring the teaching skill of faculties should be assumed by individual schools. If teachers lack such skill when appointed, provisions should be made for their instruction on teaching arts.

Integration of field experience and academic study. The amount of field experience required of students by schools is minimal. A rotating system of short periods of academic training followed by field experience might be a better way of integrating the actual practice of public health with the student's instruction in theory. A few schools have approached this program in the major fields of study, but such a modification of present schedules would entail meeting a number of new difficulties. Problems to be solved would include maintaining a 12-month staff, finding satisfactory field training centers, and preparing local health departments for the addition of field training to their activities.

Provision of continuation courses. One of the needs of the practicing public health worker is constant study to keep abreast of recent developments in his field. Responsibility for providing short continuation courses for the professional worker after graduation belongs to the schools.

The health department's responsibility. Health departments should have active recruitment programs.

They should help screen applicants and recommend to schools only those candidates who meet the requirements for advanced work. State and local public health training needs must be interpreted to budget directors by health departments. Finally, if public health objectives are to serve the continuing need for improved health, health departments and public health schools must sustain a mutual exchange of information on current needs.

Resistance to Change Requires Attention

To meet the challenge of relatively unexplored areas in public health, the content of health education of the future must secure changes in individual and group behavior and must develop more precise methods in stimulating and bringing about acceptance of such changes.

Nell McKeever, M.S.P.H., assistant chief, Public Health Education Services, Public Health Service, on behalf of herself and her chief, Mayhew Derryberry, Ph.D., spoke on what the changing public health picture means to health education programs and practices.

Health educators, McKeever believes, have the responsibility of finding ways of accelerating indicated behavior change in the way least upsetting to the established behavior pattern of the people and within their potentialities.

Future Programs

Health education will continue to look to the natural and developmental sciences for its content, but at the same time it will continue to turn to the social sciences for its methods and techniques, McKeever said.

She forecast that future health programs can expect to deal with alcoholism, and its emotional and social implications; with suburbia, and the impact of large population groups on obsolete administrative machinery; with varying population

groups, and the educational and social problems accompanying integration. Still others will attempt to bring effective public health measures to new industrial areas, overcrowded school systems, limited rehabilitation areas.

The medical education of tomorrow will demand creative, imaginative experiences to enrich the quality of medical and community leadership, she continued. Patient education, at present an example of how ideal learning situations are too often blocked by apprehensions and misunderstandings in emotionally charged situations, will present still another challenge, she noted.

Education should be ready to supply more scientific determination of the situation, to test methods to overcome the individual's and group's resistance to change, and to provide objective measurement of behavior change, she said. Education should know when to use the instruments and investigative procedures that are already available, she added.

Social Science Research

McKeever was of the opinion that the effective adaptation of social science techniques to health education will require both a closer working relationship with social scientists in practical field operations and more training in social science for health educators so that they will feel secure working in the behavior area.

Public health practitioners who are seeking an all-purpose answer to how to strengthen the process of health education may be overlooking the necessity for thoughtful diagnosis of the educational problem involved in getting people to benefit from the medical discoveries of the day, she believes.

For improvement in health to be achieved by the constructive action of individuals and groups, there is need for understanding, need to diagnose the individual's behavior, his beliefs, his motivations, his goals, and at the same time to acquire knowledge of the group's goals, traditions, beliefs, practices, values, and cultures, she said.

The public health profession, and health education in particular, can benefit from: (a) social science studies focused on the individual's attitudes and past experiences that facilitate progress or create barriers to change, (b) insight into the leadership-followership patterns established by the people, (c) exploring the accepted channels of communication, and (d) considering the objective advisability of change and the individual's or group's acceptance of change.

She cited the publications of Earl C. Kelley, Benjamin D. Paul, Fillmore H. Sanford, Kurt W. Back, Henry Clay Lindgren, Kurt Lewin, and Margaret Mead as making contributions applicable to the solution of educational problems in these areas.

"Unaccustomed as I am . . ." No Excuse at Tulane

Recognizing that knowledge in public health does not by itself always make an effective public health officer, the department of tropical medicine and public health of Tulane University offers two courses in oral communication for students working toward the M.P.H. degree.

Both courses are taught by John M. Erickson, assistant professor of business administration, who described the university's experiment in "breaking the communications barrier."

Tulane requires the oral presentation of a previously written term paper before students and faculty at the end of the academic year. Erickson said that dissatisfaction with poorly delivered papers plus realization that students were not well equipped to use the substantial body of knowledge they possessed led to making the courses a regular part of the public health curriculum.

All public health officials should be able to communicate to other responsible officials and to the general public the significance of their work

and what it means to the average citizen, he said.

If students could do no more than read their papers, they could not be effective in presenting their needs for an annual budget, in presiding over staff meetings, or in seeking luncheon club support for health campaigns, Erickson said. The Tulane courses not only duplicate these situations but provide opportunity for panel-type discussions before hypothetical audiences and for training in the handling of hecklers.

The beginning course gives practical experience in a public speaking situation and is a required 6 hours a week during the first quarter of the academic year. The work is designed to enable students to use the basic principle of communication, namely, that the speaker must secure and hold the attention of the audience on those ideas that tend to make the audience respond as the speaker wishes it to respond.

Along with the development of good speaking habits, the student learns to think in terms of his audience and to phrase his thoughts in words to which the audience will give the same meaning that he gives.

The second course teaches use of the oral communication principle in group situations. It is elective, and meets 2 hours a week in the second quarter. The student participates in informal committee work preparatory to a formal meeting in which the desired end is sought. Both situations are related to each other in organizational concept.

The courses have produced the desired development in effective oral communication, he continued. Students who were unable in the early classes to achieve directness in talking to others have changed into confident but not overconfident individuals. They show they have learned how to motivate audiences. Improved speaking manner, ease, and poise before a group, and the ability to convey ideas are the most obvious results, but most important, Erickson said, is to watch the growth of a personality as it finds new means to make life effective.

During the first sessions of a class, students show some resentment about a course which they consider out of place in a public health curriculum, he continued. The resentment is replaced by enthusiasm when they see their fellow students progress in the presentation of ideas. The improvement in the presentation of the term papers has been so marked that the faculty is convinced of the value of the courses. Graduates in their subsequent careers frequently refer to the value of the training.

Offer Sanitation Training In New York Program

New York State's comprehensive training program is offered before and during employment in order to provide competent, qualified sanitation personnel, according to Meredith H. Thompson, Dr.Eng., assistant director, bureau of environmental sanitation, New York State Department of Health, Albany.

Sanitation personnel receive coordinated and complete training. A full-time sanitation training specialist directs the program, he declared. The training unit plans, coordinates, and conducts most short courses for sanitation personnel.

Unless an efficient and continuous training program is provided, personnel cannot be expected to work at peak efficiency, he asserted.

The sanitation training program is part of the State public health training program for all department personnel. The State health department is convinced that coordinated and interdisciplinary training is basic to the team approach to public health problems, he stated. Training for health officers in New York State began in 1934, for public health nurses in 1936, for statisticians in 1938, for nutritionists in 1945, for health educators in 1948, and for sanitation personnel in 1951.

Preservice Training

Preservice training for sanitary inspectors may be an eligibility re-

quirement to a beginning permanent position. The beginning permanent sanitary inspector in local health departments must have a high school education and 2 years' public health experience, he said.

These personnel ordinarily cannot obtain the prerequisite experience, and, consequently, a 3-month training course, approved by the New York State Public Health Council, has been made available and is accepted as the equivalent of 1 year's experience. The New York Field Training Center, at Mt. Vernon, N. Y., is a cooperative venture of the Public Health Service and the New York State Department of Health. The trainee may be granted a waiver by the public health council from the necessity of a second year of experience, Thompson explained, and thus he may be employed while he obtains the second year's experience.

Inservice Training

Inservice training prepares permanent personnel for progressively responsible or specialized positions, he said. Such training ranges from short orientation courses to a full year of academic study leading to a master's degree in sanitary engineering or public health.

Orientation is scheduled as soon as possible after permanent employment. About 1 week is spent in non-sanitation units of the health department in order to give the employee needed knowledge of the overall objectives, policies, and activities of the entire department, Thompson reported.

The employee receives about 11 weeks of orientation in sanitation. He spends 3 weeks in the central office and 8 weeks in various field offices, observing and working, he explained. After this first orientation, further orientation is continued during the succeeding years on a less formal basis.

Subjects for the short 3- to 10-day nonacademic courses include epidemiology, basic bacteriology, bacteriology of water and sewage, bacteriology of milk and food, sanitary chemistry applied to water, sewage, milk, and food, statistics in sanitation, refrigeration, dairy farm sanitation, milk pasteurization, plant sanitation, food sanitation, public water supplies, basic radiological health, radiological health instrumentation, educational methods, public speaking, and public health administration.

Courses are held throughout the State to accommodate city and county personnel and are given by health department or university specialists. Although attendance is not compulsory, Thompson commented, courses are usually oversubscribed and some applicants must wait until the class can be repeated. Attendance is usually limited to from 12 to 20 persons.

All State health department personnel are permitted to apply for and, if accepted, to attend those courses in which they are interested. Generally, an employee may attend two 1-week sessions per year, Thompson said. Selected engineers and sanitarians may be authorized to attend universities and colleges for formal academic training.

Child Health Services . . .

Georgia Canvass Finds Handicapped Children

The greatest single need in the rehabilitation of handicapped children is for family counseling, stated Sam-

uel M. Wishik, M.D., M.P.H., professor of maternal and child health, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pa.

A study made by the Cerebral

Palsy and the Crippled Children's Societies of Georgia indicates that an estimated 10 percent of all children under 21 years of age have one of the 12 handicaps included in the study. Most of the handicapped children have more than one disability, he stated.

The Georgia study, according to Wishik, is the first attempt to estimate for a single community the prevalence of 12 handicapping conditions—cerebral palsy, cleft palate and lip, cosmetic abnormalities, epilepsy, eye disease and disturbance of vision, hearing impairment, heart disease, mental retardation, orthodontic and orthopedic conditions, personality disturbance, and speech difficulty.

Case Reporting

Both professional workers and interested citizens took part in the study, Wishik said. All persons in the community were requested to report to the local health department children whom they suspected of being handicapped. Copies of a set of questions were given wide publicity through churches, stores, newspapers, and other means. Parents, physicians, nurses, teachers, school health workers, neighbors, and friends of the children reported their handicaps to the societies.

Following 3 weeks of voluntary reporting, a sample canvass was made of every 10th household. The canvass technique was the more successful; only one-fourth of the handicapped children found in the sample households had been reported voluntarily. In general, handicaps found through canvass reporting included less severe ones which were not discovered by the voluntary method, Wishik noted.

Clinics

Ten clinics were set up for the 12 diagnoses. Four to ten professional disciplines were represented on each clinic team, and, he emphasized, all professional services were given without charge.

All children were classified according to a presumptive or working di-

agnosis made by a pediatrician on the basis of reports received. A sample was then drawn for each diagnosis, and 85 percent of the canvass report cases and 41 percent of the voluntary report cases were invited to the clinics. The percentages seen were 63.5 and 33.1, respectively.

The responsibilities of the clinic teams were: to confirm, deny, or correct the presumptive diagnosis; to assess the functional disability of each handicapped child; and to estimate the services needed by each child.

Among the voluntarily reported patients, diagnosis was confirmed for 63.4 percent and 77 percent were found with some handicap. These percentages were slightly lower (51.4 and 64 percent) for cases reported by canvass workers, Wishik said. But even so, Wishik found that the canvass was 50 percent more effective than voluntary reporting in discovering the needs of handicapped children.

The number per 1,000 children under age 21 with any handicap was 108. The numbers per 1,000 with each diagnosis were:

Cosmetic abnormality-----	43
Mental retardation-----	40
Personality disturbance-----	29
Speech difficulty-----	20
Eye disease and disturbance of vision-----	24
Hearing impairment-----	19
Orthopedic condition-----	17
Orthodontic condition-----	16
Heart disease-----	10
Cerebral palsy-----	5
Epilepsy-----	4
Cleft palate and lip-----	1

The average number of diagnoses per child was 2.2, and the percentages of children with multiple diagnoses were:

Number diagnoses	Percent handicapped children
1-----	32
2-----	30
3-----	19
4-----	12
5-----	6

In assessing disability, distinction was made between the child's personal adjustment to his handicap and maladjustment of his family to the situation, Wishik stated. Assessment of the degree of social rejection was based on community attitudes toward factors such as ugly appearance or strange-sounding speech. Each child's problem was considered individually. There was little correlation between the degree of physical disability and the child's vocational limitation, his family's reaction, and society's rejection.

The association of mental retardation and personality disturbances with certain physical handicaps emphasizes the importance of psychology and psychiatry in crippled children's programs, Wishik said.

Estimates of services needed by each child were made at a staff conference. All the children needed diagnostic appraisal and a plan of care. About 70 percent needed counseling or guidance or their parents needed education; about 10 percent needed institutional care, he stated.

To meet the need for family counseling, new administrative patterns were recommended, such as local field extensions of a rehabilitation center, direct focus on patients by social workers in health departments, major units for the handicapped in voluntary child and family agencies, and specialized programs attached to a coordinating or referral agency. "Close working relationship between counseling and other service programs is, of course, essential," Wishik emphasized.

Childhood Chronic Illness Control Progress Reviewed

Chronic illness and disability are not limited to old age but are found also in children and young adults, stated Thomas E. Shaffer, M.D., professor, department of pediatrics, College of Medicine, Ohio State University, Columbus, in reviewing progress

in controlling the common chronic diseases of childhood.

Although most chronic diseases cannot be cured, many can be prevented, Shaffer said. The progress of many more can be halted, and handicapping disability can be prevented if the disease is discovered and treatment is begun early. Periodic health appraisals and medical screening of school children are discovering many chronic illnesses during childhood, before the disease process is far advanced, he added.

"We know how to control rheumatic fever," he said. The problem is recognition of the streptococcal infections in children, administration of penicillin when the infections occur, and teaching parents the importance of continuing prophylactic treatment even though their children appear to be in good health. Diagnosis of rheumatic fever on physical examination is difficult, Shaffer stated, but reliable and clinically practical laboratory tests are available and can be carried out in most laboratories.

Congenital Heart Disease

X-rays, often supplemented by injection of materials into the blood stream to outline blood vessels and heart cavities, examination of blood samples taken directly from the heart, and electrocardiograms have made it possible to diagnose malformations of the heart with "almost the exactitude of engineering," Shaffer continued. Persons formerly faced with lifelong chronic disability because of malformed hearts can now be made normal, physically, through surgery, he stated.

Epilepsy and Diabetes

The electroencephalograph for diagnosis and medication with new non-sedative drugs are the two most notable recent advances in the control of epilepsy, Shaffer said. None of the antiepileptic drugs in use today cause mental deterioration, he stated, and all epileptic manifestations can usually be suppressed with the newer drugs, singly or in combination. Radical surgical procedures

are available for those who do not respond to medical treatment.

Medical control of the disease has made it possible for epileptics to go to school with other children, to develop normally, and to go on to normal employment later in life, Shaffer said. Public realization of the fact that only a small percentage of epileptics are retarded mentally is increasing.

The development of insulins that can be taken only once a day is probably the most important advance in the control of diabetes since the discovery of insulin in 1922, Shaffer said. So-called regular insulin had to be given before each meal and often at bedtime. Since 1 child in 2,500 under the age of 15 years has diabetes, the effect of such a radical change in the insulin schedule upon the feelings of children about their disease and their social relationships in school and elsewhere is obvious, Shaffer stated. The current tendency to permit growing diabetic children to choose their food has also helped them to be considered as normal children, particularly in the classroom.

Shaffer said that medical science still has a "giant-size" step to take, the discovery of insulin that can be taken by mouth.

Cerebral Palsy and Tuberculosis

The rehabilitation of cerebral palsied children so that they can live and work to the limit of their capacity is an outstanding advance in the cooperative treatment of chronic disease, Shaffer stated. Another milestone is the combination of special education and therapy—physical, occupational, and speech—in the treatment of cerebral palsy.

Location of active tuberculosis among adults and their prompt isolation and treatment have greatly reduced the chances of infection in children, Shaffer said. Drugs can prevent tuberculous infection, even as they halt progress of the disease among adults, he said.

Obesity and Cancer

Obese children are no longer con-

sidered to be suffering from endocrine disorders, and treatment is directed toward controlling calories rather than prescribing thyroid and sex gland hormones, Shaffer stated. Obesity in childhood is often the result of the emphasis on weight gain in infancy, he said, and parents come to believe that plumpness is synonymous with health and happiness even after their children are no longer infants.

Health education and periodic health examinations contribute to the control of cancer, one of the most frequently fatal diseases of childhood. Radiation of tumors and surgical removal of new growth save the lives of children whose cancers are diagnosed in early stages, and chemotherapy has prolonged life in certain blood diseases. Medical treatment for the present is limited to the means of interrupting or reducing the progress of cancer diseases, Shaffer said in conclusion.

Cites Ten Principles For Rehabilitation

Recent advances in rehabilitating chronically ill adults may be applied to restore handicapped children to normal daily living and activities, according to representatives of the bureau for handicapped children, New York City Health Department.

Discussing the new techniques were: Helen M. Wallace, M.D., former director of the bureau and now director, department of public health, preventive medicine, and industrial hygiene, New York Medical College, and Jerome S. Tobias, M.D., bureau consultant in physical medicine and rehabilitation and professor and director, department of physical medicine and rehabilitation, New York Medical College.

Also: Robert S. Siffert, M.D., senior orthopedic consultant to the bureau; Margaret A. Losty, R.N., coordinator of the bureau's hospital consultation program; and Caroline H. Elledge, chief medical social work consultant to the department.

Ten Principles

They outlined 10 basic considerations for administrators and clinicians planning for the maximum restoration of handicapped children in the community.

1. The employment of a consultant in physical medicine and rehabilitation is as necessary as other medical consultants. His assistance might develop and evaluate physical medicine and rehabilitation services and develop standards for a department of physical medicine and rehabilitation. He might supervise the training in rehabilitation techniques for personnel in health departments, institutions, and crippled children's agencies.

2. Personnel on the staffs of institutions, crippled children's agencies, and health departments need training in the principles of maximum self-sufficiency which are being taught to patients. With the newer knowledge of rehabilitation techniques, the teaching of activities of daily living, such as feeding, dressing, toilet care, wheelchair transfer, ambulation, gait training, to children in institutions and at home could become dynamic.

3. The training program should be developed, both for the faculty and trainees, along the multidisciplinary approach, which requires a battery of professional skills. The approach should result not in replacement of one type of professional worker by another but rather in a supplementation of one by the other and should apply to the initial evaluation of the patient, periodic reevaluation, continuous supervision, and counseling of the patient and his family.

4. Services for the rehabilitation of handicapped children and adults must be coordinated and integrated. Chronic illness does not magically begin at any age. The artificial separation of the "under 21" and "over 21" age groups merely confuses community planning with the resulting duplication of efforts, funds, and services.

5. Since rehabilitation of the handicapped child is frequently not

accomplished on a short-term basis, long-term care is often essential. Frequently the term has incorrectly meant long-term institutional care. It should imply the necessity of continuity of care, supervision, and rehabilitation for the child whether he is an inpatient or outpatient, whether he is at home, in school, in job training, or at camp.

6. If medical advances are to be made in improvements of methods, and if fiscal authorities and the public are to be convinced of the value of rehabilitation programs, studies are needed to develop even such basic evaluation data as the rehabilitation results to the individual patient for a given period of time, the most effective and successful techniques in certain types of disabilities, and the cost of rehabilitation per patient for each diagnostic group, by institutions and so forth.

7. The community's existing services and resources, available personnel, and public and professional interest are key factors in deciding priorities. A priority system must be established in the early stages of a program. Carefully worked out standards are essential to guide participating institutions as well as accrediting groups in approving adequate acceptable services for a payment program.

8. Quantitative and qualitative knowledge of existing services and resources and of current gaps in patient care should include: services provided by the hospitals and convalescent homes, resources for the homebound group of children, services provided at school, vocational resources, recreational programs, transportation facilities, long-term residential or custodial services, and the foster and child welfare services.

9. Close cooperation with the State and local agencies responsible for the administration of the newer Federal legislation would seem essential. The Hill-Burton and Vocational Rehabilitation Acts provide a means of improving and expanding services for handicapped children. Personnel engaged in crippled chil-

dren's programs already have considerable knowledge about current services and facilities.

10. Purchase of care on a cost basis is vital, for if this cost, usually high, is not met in some way, then services are automatically decreased by reduction of personnel. Some essential services therefore will not be provided, and rehabilitation will lose effect. Logical sources, in addition to the patient and his family, are the categorical voluntary agencies and governmental agencies. Official and voluntary sources of funds should be regarded as supplementing each other in their grants, payment of salaries, development of new services, strengthening of existing services, purchase of equipment, research projects, training of personnel.

Immunization Programs Miss Many Infants

Immunization programs against diphtheria, tetanus, pertussis, and smallpox cannot be assumed to reach all of the children in a rural area during the first year of life, according to Alice B. Tobler-Lennhoff, M.D., deputy health officer of Maryland. In fact, she said, if the experience of one Maryland county is typical, they fall far short of the goal.

Every effort was made to immunize every child in rural Calvert County, Tobler-Lennhoff stated. A study showed that 59 percent of all the children born in the previous year (1952) had received partial immunization and only 44 percent had received the complete immunization course (3 injections). Tobler-Lennhoff also found that the smallpox vaccination program in this county was even less effective; only 107 out of the 412 in the study group had been vaccinated.

The immunization and smallpox vaccination status on December 31, 1953, of the 412 children born in 1952 in the study area—164 white and 248 nonwhite—are shown in the accompanying table.

During the past 5 years the county health department, according to Tobler-Lennhoff, has been conducting child hygiene conferences and has offered pediatric consultation to parents. Clinics in speech, hearing, mental hygiene, and vision are held at regular monthly intervals, in addition to a bedside program. All new parents were informed by postcard about health department facilities for their infants and given a recommended immunization and vaccination schedule.

Of the nonwhite children, 60 percent had received some immunization while only 55 percent of the white children had. However, 47 percent of the white group and only 40 percent of the nonwhite group had completed their immunizations.

Twenty-two of the white children were immunized by health department personnel and 67 by private physicians, whereas 131 of the nonwhite were immunized by the health department and 22 by private physicians. Eleven white and 65 nonwhite children were vaccinated by the health department and 22 white and 9 nonwhite by private physicians.

Of the 124 children neither immunized nor vaccinated by December 31, 1953, 24 were reported as having never been sick and having no medical supervision, according to the answers on a questionnaire. A large number, though seen by physicians for illness, rarely had checkups. The same was true for the partially im-

munized. A majority of the children were taken to their family physicians or clinics fewer than 6 times a year.

Despite intensive educational efforts, 41 percent of the children were not immunized by December 31, 1953, when ideally all immunizations should have been completed. Data not included in this study show that a large number of these children did receive immunizations in the early months of 1954.

Vaccination v. Immunization

Reasons given by Tobler-Lennhoff for the difference in accomplishment between vaccination and immunization included the following:

Smallpox vaccinations are not given during the summer months; during the winter months they are often put off on account of illness.

DTP immunizations start earlier, at the age of 3 months, giving those who attend clinics or go to a doctor irregularly a better chance to get at least a partial immunization.

Absences of known instances of smallpox for many years may have engendered some indifference to vaccination.

Ignorance of the State law requiring vaccination within 1 year after birth, its lack of enforcement, and the rigid enforcement of the school law requiring vaccination before a child enters school may have led to a general belief there is no need for early vaccination.

Technical Development Key To Child Health Plans

An effective national or international maternal and child health program must take into account the stage of technical development in a country, according to Louis J. Verhoestraete, M.D., M.P.H., medical officer, adviser in maternal and child health, Pan American Sanitary Bureau, Regional Office of the World Health Organization, Washington, D. C.

Infant and childhood mortality patterns are closely related to technical and economic advances, he found, in comparing areas of different degrees of technical development.

In areas, containing one-fifth of the world's population, the infant death rate is lower than 50 per 1,000 live births; in other areas, with three-fifths of the world's people, there are about 100 or more infant deaths per 1,000 live births.

In the technically less developed areas, the mortality pattern points to emphasis on programs that will control the major communicable diseases and improve sanitation and nutrition, Verhoestraete observed.

Excess mortality in these areas extends throughout childhood but focuses particularly on the age groups of 0 to 1 year and 1 to 4 years, the data showed. The main causes of childhood mortality are the gastrointestinal, respiratory, and other infectious and parasitic diseases, all preventable and essentially dependent on environmental circumstances.

In the technically advanced countries, the low mortality rates in the 1 to 4 age bracket reveals that environmental causes of child mortality are well under control. Neonatal mortality, less dependent on the safety of the general environment than childhood survival, has become the outstanding problem, he said.

Expansion of general health programs and development of specific maternal and child health activities are the remedial measures for the high childhood mortality in the tech-

DTP immunization and smallpox vaccination status of 412 children born in Calvert County, Md., in 1952 on Dec. 31, 1953

FETAL DEATHS

nically less developed areas, he observed.

In cognizance of probable slow development in many areas, particularly in rural localities handicapped by limited health and medical facilities, Verhoestraete suggested that the immediate programs aim at well-defined and limited objectives rather than an inclusive approach.

Proposed Measures

He offered a number of measures that may be applied by a team consisting of a semiprofessional nurse, an untrained village midwife, a teacher, and a sanitarian, with medical advice available on a visiting basis.

Breast feeding, he said, should be accepted as the surest life-saving device in an unhygienic environment since it provides safe nutrition and reduces opportunities for gastroenteric infection.

The nutritional problems of the weaning and postweaning periods, he continued, are most important in these areas, and improved nutrition for the lactating mother will help her feed her child more successfully for longer periods. Early feeding with available animal or vegetable protein, often imperative, should be truly supplementary rather than a replacement of breast feeding at 5 to 6 months.

In preventing the spread of diarrheal disease, he said, recent evidence has indicated that quantities of readily available water for personal and household use may be more effective than a limited supply of sanitary water. This knowledge, he believes, will influence future water supply policies in rural areas.

For children with diarrhea, he suggested a treatment method that may be safely applied by semiprofessional and auxiliary nurses to reduce fatalities. Rapid dehydration is a major contributing factor to deaths from diarrhea, he said. A simple method of rehydration consists of early ingestion of water with sugar and salt or of a simple glucose and electrolyte mixture.

Verhoestraete advocated caution

in trying to promote with too much zeal the Western patterns of child rearing, which are themselves still in the formative phases.

In the fields of "harmonious growth and development," women in the technically less developed areas are not necessarily at a disadvantage, he said. Many of them seem to have a capacity for adjusting, without stress, to their pregnancy and prospective childbirth and to establish with ease stable emotional relationships with their newborn infants. In these circumstances, Western women seem, at present, to be more frequently in need of professional guidance and reassurance, he pointed out.

Fetal Death Factors Studied in New York

Ectopic pregnancy and spontaneous fetal death occur more frequently among nonwhite women than among white women, according to a study of the 58,285 fetal deaths reported in New York City in 1952-54 (see table).

The ratio of ectopic pregnancies to 1,000 live births was 6.8 for nonwhite women and 2.2 for white women. The spontaneous fetal death ratio was 153.5 for nonwhite women and 72.9 for white women.

This study, which provides such data on a communitywide basis for the first time, was reported by Carl L. Erhardt, director of the bureau of records and statistics, and Harold Jacobziner, M.D., assistant commissioner for maternal and child health services, New York City Department of Health.

Other findings of the study are as follows:

1. Ectopic pregnancies increase in frequency with advancing age of the mother; the rate of increase is highest for first pregnancies. They decline in frequency with an increase in the number of pregnancies.

2. Spontaneous fetal deaths also increase in frequency with advancing age of the mother. However, they rise in frequency with an increase in the number of pregnancies in the young age groups (15-19, 20-24, and 25-29) and decline with an increase in the number of pregnancies in the older age groups.

3. A history of previous fetal loss increases the risk of loss in the current pregnancy. The ratio of ectopic pregnancies to 1,000 live births rises from 2.4 for women who have no history of a previous fetal loss to 9.5 for those who have had three or more unsuccessful pregnancies. The ratio of spontaneous fetal deaths increases from 66.1 for women with no history of a previous fetal

death to 765.4 for women with a history of four or more previous fetal deaths.

Optimal Age for Pregnancies

The data on spontaneous fetal deaths for white women indicate that there is an optimal age for child-bearing, Erhardt and Jacobziner declared. The data, they said, indicate first pregnancies are desirable before the woman is 25 years old; second to fourth pregnancies, during the 10-year interval from age 25 to 34; and the fifth or more pregnancies, between the ages of 35 and 39 years.

The data for nonwhite women are less clear cut, they remarked. However, there seems to be the least fetal loss for first pregnancies when the mother is less than 20 years of age.

The sharp rise of fetal deaths with age among nonwhite women as compared with the slower increase among white women may be due to earlier effects of a higher incidence of disease and poorer nutrition among the former, they said.

The finding of a distinct relationship between previous unsuccessful pregnancies and early fetal death confirms observations of many other investigators, they noted. They advised that women with such a history and their husbands be given special attention in preconceptional treatment clinics. Both the wife and the husband should be studied, they said, since defective genes or psychological or biological disturbance of either may be a causative factor in fetal loss.

A popular misconception, she pointed out, is the belief that if a solvent or cleaner is not flammable it is safe. Stamp collectors, craft hobbyists, and insect collectors too often expose themselves to injurious dosages of carbon tetrachloride, Gleason pointed out, explaining that safety engineers have a simple recommendation for the safe use of the halogenated hydrocarbons: "If you can smell the odor, you are breathing too much of it."

She urged that amateur gardeners and farmers be made more aware of the toxic effects of nicotine and the dusts and vapors of many insecticides, such as the organic phosphorous compounds. In fact, Gleason said, it would be interesting to study the relationship of careless exposure to dangerous materials to the many tractor accidents on small farms.

Another study she thought might yield meaningful information would be a study of the causes of the falls from ladders by amateur painters. She thought that the breathing of turpentine fumes near a hot ceiling or in a badly ventilated room might be one of the leading causative factors.

Much has been done, Gleason said, to make toys for children safe, but intensified efforts by public health workers are needed to educate the adult public.

Accidental Poisoning . . .

Cites Health Hazards In Home Hobbies

Although hobbies and do-it-yourself activities have made homes more interesting places to live in, they have also introduced new hazards to health, according to Marion Gleason, research assistant in the department of pharmacology and toxicology, University of Rochester (N. Y.) School of Medicine and Dentistry.

Many toxic materials which may predispose the user to shop accidents are widely used by home hobbyists today with little or no regard to the manufacturer's warning labels, she said. Episodic or chronic exposures to many "harmless" chemical products often result in drowsiness, dizziness, lack of coordination, psychic disturbances, and impaired vision. Any of these symptoms can result in deviation from protective habits or conduct, Gleason stated, and may mean the difference between safety and serious injury.

Thousands of products, such as solvents, rust removers, paint thinners, insecticides, and fumigants, not only can cause serious injury when instructions for use are ignored, she said, but in lesser exposures are capable of bringing out less obvious accident-predisposing effects.

"Doctors are aware of the toxicology of such agents as carbon tetrachloride, nicotine, methyl alcohol, and the organic phosphorous compounds, and the injuries to the liver, kidneys, heart, and brains from the inhalation and skin absorption of such poisons are fully described in medical literature," Gleason stated. "But the symptoms of nephritis and hepatitis, obscure anemias, amblyopia, cardiac failure, and some virus infections closely resemble those of exposures to a number of chemicals in common use in homes and farms," she said. "Thus, the causative factor in the illness may be overlooked by both the patient and the attending physician."

Data on Poison Mishaps Do Not Show True Rate

Accidental poisoning from farm work does not appear to be a major problem, according to L. F. Garber, M.P.H., chief of the industrial hygiene service, Missouri Division of Health, but farm safety measures designed to prevent poisonings should be improved and applied.

He pointed to advances in agricultural chemistry resulting in frequent introduction of new pesticides, defoliants, fertilizers, fumigants, and other potentially toxic products into farm operations.

Garber insisted that the signifi-

cance of poisoning as a cause of farm accidents has been minimized because of the large number of accidents resulting from farm machinery. The difficulty of obtaining adequate statistical data on farm poisonings needed to determine the relative importance of this problem is increased by the necessity of separating work accidents from home accidents and of establishing conclusions based entirely on mortality rates.

National Safety Council statistics, Garber said, show that approximately 50 percent of the 3,800 farm accident deaths occurring in 1954 were due to motor vehicle accidents, the result, in part at least, of increasing mechanization of farm tasks. Similarly, he reasoned that rapid advances in the field of agricultural chemistry and the increasing tonnage of chemicals used for agricultural purposes may result in more poisoning cases on farms.

Lack of clear definition of accident sites probably caused some overlapping so that an accurate analysis of data cannot yet be made, Garber indicated, pointing out that the International Lists of Diseases and Causes of Death excludes the "home" and "home premises" from the definition of "farm."

"There must be some overlapping between what is farm and what is home," he said, adding that "even if morbidity reports were submitted by physicians, the tendency of the small farmer to seek medical care only in emergencies, would probably affect the picture."

Substances Responsible

Chief among the groups of compounds listed by Garber as introducing poisoning problems on the farm are the organic phosphate and somewhat less toxic chlorinated hydrocarbon insecticides. Garber discussed investigations of the toxicity of, and exposure to, these insecticides in farm work.

He cited, among others, a study of exposure to parathion and cholinesterase response in Quebec apple growers, in which it was concluded

that marginal intoxication was experienced by a group of 1 female and 32 male adults. Also, a study of 258 persons subjected to varying degrees of exposure to parathion in Washington apple orchards led to the conclusion that average cholinesterase values for those persons who were known to have had definite and consistent exposure showed significant reduction during the period of exposure.

In California, occupational diseases due to organic phosphate insecticides rose from 20 percent in 1950 to 40 percent in 1953. The California State Department of Public Health reported 391 cases of occupational disease caused by agricultural chemicals in 1954. Of 122 cases of systemic poisoning included, 101 cases were due to exposure to organic phosphates, with parathion exposure associated with 85 of the cases. Six reflected exposure to chlorinated hydrocarbons.

Other cases of accidental poisoning on farms Garber termed "miscellaneous," and listed under this heading lead poisoning among apple orchard workers, methyl bromide poisoning among fig processors, and ethylene chlorohydrin poisoning among workers treating seed potatoes. He called attention also to the condition sometimes described as "thresher's lung," resulting from the inhalation of dust from moldy hay or straw, and to cases due to familiar causes such as carbon tetrachloride used as a seed fumigant, carbon monoxide from internal combustion engine exhausts, and carbon dioxide from fermenting silage.

Midwest Incidence

Garber felt that the problem of poisoning on the small midwestern farm is of less magnitude than that encountered in other States. An examination of farm work accidents in Kansas in 1930-51 disclosed 7 deaths from absorption of poison gases and 4 deaths by solid or liquid poisons out of a total of 1,810 deaths.

Iowa reported 24 chemical-caused fatalities and 15 deaths from car-

bon monoxide poisoning in a total of 2,181 fatal work accidents among farm residents in 1940-53, while only 4 deaths by poisoning in 245 farm fatalities took place on Missouri farms during 1952-54.

Garber was of the opinion that the greater use of seasonal and temporary employees with little or no knowledge of farm operation was one of the factors for the relatively high frequency of poisoning accidents in Western States.

Poisoning Prevention Role Of Health Agency Stressed

Poison control activities which health departments and agencies can utilize effectively were reviewed by Ralph K. Longaker, M.P.H., chief, Home Accident Prevention Section, Public Health Service, and Charles M. Cameron, Jr., M.D., M.P.H., associate professor, University of North Carolina School of Public Health.

Official health agencies can be instrumental in reducing the number of accidental poisonings, they said. Cooperating with other groups, such agencies might determine the nature and extent of local hazards and develop professional and community education programs designed to alert the public, with appropriate emphasis on those which are seasonal or new.

Several health departments, they said, have made successful attempts to limit poisoning accidents. Campaigns in New York City and Arkansas have reduced dangers from wornout gas appliances and improper fuel oil storage, respectively.

Gases cause about half the annual 2,700 poisoning deaths. Victims of gas poisoning, which is most frequent in winter, are generally adults. Seventy-five percent of the gas poisoning deaths occur in the home.

Of the fatal poisonings from liquids or solids 80 percent occur in or around the home, and victims are usually preschool-age children. Sea-

sonal trends in liquid or solid poisoning accidents are not as pronounced as in gas poisonings, although there are apparent changes in seasonal exposure to various types of toxic liquids or solids.

More definitive epidemiological and etiological data on specific poisoning hazards in particular localities should be collected, Longaker and Cameron said. Sources for such data include death certificates and the files of local emergency clinics, police and rescue crews, physicians, and hospitals.

"If these reporting systems provide complete or representative coverage they may be developed on a continuing basis to provide a measurement of trends within the problem. They become a source of background data for the educational phases, and can be used as a means of evaluating control measures when they reflect significant decline or variation."

They believe such studies could provide health departments with working diagnoses of community problems which might be used as bases for planning measures to teach the public necessary safety techniques.

In addition to making use of public and private educational systems, home demonstration clubs, community health councils, organizations of parents and teachers, and other institutions, educational efforts should utilize the direct relationships of physicians, especially pediatricians, and professional public health personnel to the public, they said.

Urges Coordination In Poison Control

The increasing production of new chemicals and old standbys in new combinations necessitates national coordination of poison control efforts, according to George M. Wheatley, M.D., M.P.H., third vice-president of the Metropolitan Life Insurance Co., chairman of the Subcommittee on

Chemical Poisons, American Public Health Association.

Valuable and harmless as all these chemical products are when properly used, Wheatley said, the problem is their misuse, particularly in the home.

Aspirin, kerosene, and lead poisoning are the major causes of death (fig. 1), Wheatley stated. About two-thirds of the deaths from accidental poisoning could be prevented if acetylsalicylic acid, the barbiturates, kerosene, lye, lead, and arsenic were kept out of reach of young children, he said.

Mortality from misuse of chemicals is only part of the picture. There are hundreds of nonfatal home-poisoning accidents for every fatality, according to recent data, Wheatley stated. More than one-third of the total number of deaths from accidental poisoning are among children under 5 years of age, he said. Here again the number of deaths are few in comparison with the number of serious hospitalized cases (fig. 2).

Control Measures

Various medical and governmental groups have made efforts to control the hazards of accidental poisonings. The main Federal legislation, since the laws of 1906 and 1910, is the Federal Insecticide, Fungicide, and Rodenticide Act of 1947. This law authorizes the Department of Agriculture to require adequate toxicological information, testing, and labeling of new pesticides before they may be sold.

Another important poison control measure, the Federal Caustic Poison Act might be properly reviewed and broadened in the light of current conditions, Wheatley said in pointing to chemicals, which though non-corrosive, may be fatal in relatively small doses.

Recent measures by medical groups began with the American Academy of Pediatrics Committee on Accident Prevention organized in 1950. The American Medical Association's Committee on Pesticides was organized to attack the problem on a

Figure 1. Types of accidental poisoning deaths in 834 children under 5 years of age in the United States, 1949-50.

wider front. By 1951, these two committees were working closely with the home safety conference of the National Safety Council and the Food and Drug Administration on various aspects of child poisoning. In 1952 the Lead Industries Association joined the circle along with other groups and individuals.

Poison Control Centers

A poison control center was established in Chicago in 1953, experimentally as one element of the program of the committee of the pediatricians, which also organized committees at State and urban levels. The Chicago committee prepared a manual on the treatment and recognition of toxic agents, which has been used in cities.

The Chicago experience has served as a guide to the formation of 13

other poison control centers, Wheatley said. These centers are located in Washington, D. C., Boston, Mass., Dallas, Tex., Durham, N. C., Indianapolis, Ind., Louisville, Ky., New York, N. Y., Phoenix, Ariz., Grand Rapids, Mich., New Bedford, Mass., Springfield, Ill., Newark, N. J., and Harrisburg, Pa.

Future Action

Recently, a Subcommittee on Chemical Poisons was formed by the American Public Health Association's Committee on Research and Standards, Wheatley said. It will give its attention to the epidemiology of chemical poisoning and to the role of health departments in this field.

The development of a clearing-house for the control activities of official health agencies is another ob-

jective. To expedite these efforts and to avoid overlapping or duplicating work done by other groups, an exploratory meeting of representatives from the official and voluntary national organizations most concerned has been sponsored by the APHA subcommittee.

The continued expansion of poison control centers will provide a way of coping with emergencies and will also serve the ultimate aim of prevention, Wheatley said.

Laws Protect Food From Pesticides

"If all the laws are observed the hazard associated with the use of pesticides in the food processing industry is essentially nil," said Wayland J. Hayes, Jr., M.D., Ph.D., chief, Toxicology Section, Communicable Disease Center, Public Health Service, Savannah, Ga.

Sanctions on pest control in food handling industries are associated with law and consumer acceptance. The latter is the more subtle and powerful of the two, he commented. The final justification for pest control in food handling, he explained, is esthetic; the public believes that food should be clean and wholesome.

Laws on pest control and other aspects of cleanliness in food handling have, he said, several functions: to set standards of performance, which often represent a compromise; define technical details necessary to achieve the standards; establish administrative procedures; and promulgate sanctions against the small minority who might otherwise violate the regulations.

Legal Provisions

The Federal Food, Drug, and Cosmetic Act is the main law requiring pest control in all interstate food handling industries, Hayes said. More than 80 percent of the food seizures in 1950 were made because the food contained insect parts, rodent hair or excreta, or was decomposed, he noted.

However, he pointed out, the use of baits is the method of poisoning insects, or rodents, for it is only the addition of poison or chemicals to material to feed and eat to make it toxic. In the United States, he noted, it is generally contended that no addition of poison to food is necessary or tolerable after harvesting.

Many States have laws similar to the Federal statute, he said, and various local codes supplement them. The local codes are very specific concerning floor and working surfaces, special food-handling equipment, and many other house-keeping details, he said. Sanitation, by reducing to a minimum the food and harborage available to insects and rodents, is the most important single factor in the control of pests, he declared. Nevertheless, in plants handling many tons of products there is bound to be some spillage.

The Federal Insecticide, Fungicide, and Rodenticide Act is essentially a labeling act for chemicals sold in interstate commerce to be used as pesticides. It provides for the registration of pesticides if, among other things, they are effective for the uses advocated, and they are safe when used as directed, he said.

Hazards of Misuse

There are hazards to the operator or to the food consumer which might follow neglect of regulation. Details on the toxicity of the older pesticides may be found in pharmacology texts, he stated, and information on the toxicity of the newer pesticides is available in the Clinical Memoranda on Economic Poisons, which may be obtained on request from the Technical Development Laboratories, Communicable Disease Center, Savannah, Ga.

Although nearly all the pesticides may be fatal if swallowed, there is small chance that these will be swallowed in lethal doses except with suicidal intent, he declared. Probably the most common danger to anyone applying insecticides or fungicides is allergic reaction following direct exposure. This danger is

presented by the use of baits, he said, for it is only the addition of poison to food material to make it toxic.

Fungicides, he pointed out, are used on food crops and dried fruits, and are dangerous to the operators. Fungicides are not such as to thrill anyone of action, not so well there is usually a delay of 6 hours after exposure before illness sets in.

Hayes said there was a trend toward the use of fast-acting rodenticides, such as which are slow to act but at as effective as the dangerous acting agents such as sodium acetate (10-0).

He said fly baits using TE

Mental Health

Links Mental Deficiencies To Maternal, Fetal Factors

That there is a relationship between mental deficiency and abnormal conditions existing during the fetal and neonatal period is indicated by results of a controlled study of the birth certificates and hospital records of mentally defective children in several institutions in Baltimore and in two Maryland institutions for mental defectives, reported Abraham M. Lillienfeld, M.D., and Benjamin Pasamanick, M.D.

Dr. Lillienfeld is chief, department of statistics and epidemiological research, Roswell Park Memorial Institute, Buffalo, N. Y., and Dr. Pasamanick is professor of psychiatry and director of scientific research, Ohio State University College of Medicine, Columbus, Ohio. The studies

medicine, which speaks of a "healthy person in a healthy society," and which is based on sounder logic, Foster thinks, than a "healthy mind in a healthy body."

Long-Term Research

Foster noted a lack of cooperative specialization, on the part of the sciences and professions concerned with family life, in understanding the etiology of individual and social problems. He told how professional unionism among the organizations most concerned with family life led them to function as pressure groups and to include as members only those who met certain standards. These agencies, because of their fragmentation, are not helping the family do its important job of child rearing and maintaining itself as a unit over a long period of time, he commented.

"We need to set up centers to study how to get mental and other health practices incorporated into the daily living of everyone in our society," he urged. He suggested evenly distributed financial support for research, training, and treatment, and that, as the middle step between research and application, long-time projects be conducted over several generations. These might help demonstrate how individuals, through family experience, can grow up to become mature, mentally and physically healthy people; how the resources of the community can be analyzed and used to further the objectives of better health through education; and how existing organizations and the community can utilize the results of such effort.

Health Service Improved Through Group Learning

The use of a teaching experience which was part of the day-to-day program of a local health department, to improve a health service while the service was given, was described in a discussion of group learning in mental health practice.

The 5-year group project in the well-baby clinics of the Louisville

and Jefferson County Board of Health, Louisville, Ky., served as the basis for the discussion presented by Marie Goik, R.N., M.S., nursing consultant, United States Children's Bureau, San Francisco, Calif., and Henry H. Work, M.D., associate professor of psychiatry, University of California Medical Center, Los Angeles, Calif.

Objectives of the Kentucky mental health study, they said, were to improve methods of teaching physicians and nurses, to integrate general public health nurses into teaching programs, and to present methods of caring for mothers and babies so that clinic services were supplemented by mental health values. The study proved the value of the technique in intensifying and consolidating learning experiences, they said.

Students included graduate and student nurses, medical students, and residents in pediatric training. The teaching staff consisted of a pediatrician-psychiatrist, a psychiatric social worker, and a public health nurse trained in mental health nursing, they stated. Consultation services of a psychologist and a nutritionist were available. Administrative personnel participated in the planning, thus facilitating decisions as to time and personnel allocated to the project.

The major teaching effort was directed toward the training of residents in pediatrics and the public health nurses who worked in the well-baby clinic. Seminars for each group were held over a 1-year period to give the students a general understanding of the growth of a child and the mental health problems of mothers and children, Goik and Work stated. Courses in personality development were included for all students.

The seminars were held concurrently with the clinics. Students were separated according to disciplines and teachers were matched to the student groups. In the early seminars, there was a tendency to underestimate the students' knowledge; later periodic review was re-

quired to determine if instruction was proceeding too fast, they said.

Seminars demonstrated individual physical and psychological development and the relationships established during growth. Case examples and audiovisual material were used and, whenever possible, clinic cases were linked to mental health films illustrating the principles involved. Films were chosen which might aid the students to understand the cases seen in the clinics.

Since it was not possible for formal teaching to precede practical application of knowledge, difficulties encountered in the clinic were discussed in the seminars, they said. This enabled the teaching staff to modify its work so that principles were more closely linked with practical application.

Clinics

The actual operation of all well-baby clinics in the Louisville and Jefferson County Board of Health was entrusted to graduate nurses, Goik and Work said. Assignment of pediatric residents to individual clinics for 6-month periods enabled the residents to become acquainted with clinic personnel and with the patients.

A member of the teaching staff was present during the physician's examination or worked with the nurse in her direct contact with the patient, they reported. Such observation of treatment, examination, or technical procedure resulted in a better appraisal of the student's clinical approach. It also gave the instructor an opportunity to evaluate the patient and to assist the student in contacts with patients, teaching the student the value of giving attention to minor and seemingly unimportant comments of patients.

At the close of each clinic, the teaching staff, the residents, and the nurses discussed the patients and the treatment procedures, they stated. Later, members of the teaching staff might accompany the nurses, at their request, into the patients' homes.

Postclinic Conferences

Postclinic conferences brought together the accumulated knowledge of students from all disciplines. It provided for discussion of the patients and the reactions of the members of the group to one another, Goik and Work stated. The teaching team tried to keep the discussions patient-centered. Even when personal needs of the students arose,

the teaching staff used examples of similar situations among patients and fellow students instead of centering the discussion on the student involved, Goik and Work stated.

In these conferences, they said, both physicians and nurses learned how to deal with various types of clinic patients. The teaching team was able to improve understanding of physicians and nurses for each

other's difficulties and to help the patients. Nurses and physicians in turn presented cases to the group and shared their experiences and feelings. Having all student groups represented in the conferences facilitated teaching and assistance to the patient as well as understanding between representatives of the disciplines on the teaching team.

Mental Health Section Established

Giving action to the theme of the 1955 conference—Where Are We Going in Public Health?—the governing council of the American Public Health Association established a new APHA section on mental health when it met in Kansas City.

Establishment of the new section recognized the need for intimate integration of mental health within the structure of the American Public Health Association. Chairman of the section is John D. Porterfield, M.D., director, Ohio State Department of Mental Hygiene and Correction, Columbus.

Prior to the meeting of the governing council, two regular program sessions and a luncheon were devoted to mental health needs within public health services.

The luncheon meeting was addressed by Leonard A. Scheele, M.D., the Surgeon General of the Public Health Service. Dr. Scheele traced the developments in mental public health of which the formation of the new section was the logical conclusion.

In the program sessions, papers were presented on the social drift of schizophrenia patients, the distribution of elderly adults in the population, and their health and mental health problems.

Two other papers took up the subject of mental deficiency: One dealt with its distribution in a county, and the other with the relationship between the hypothesis of fetal wastage and mental deficiency. Another paper discussed prematurity and its relationship to mental deficiency and various neuropsychiatric conditions.

Certain of these studies will appear in forthcoming issues of the *American Journal of Public Health*, and others have been included in the news coverage of

the annual APHA conference appearing in this issue of *Public Health Reports*.

Other activities at the conference reflected the growing concern for coordinating mental health and public health activities.

A full session of the APHA public health nursing section listened to a panel discussion, led by Ira V. Hiscock, Sc.D., on the role of the public health nurse in mental health.

The Committee on Research and Standards heard and accepted a report on mental health.

The Committee on Administrative Practice established a subcommittee on mental health. The committee, like the governing council, is one of the basic policy groups in the association. It is responsible for many of the publications issued by APHA.

Other officers of the new section are: Paul V. Lemkau, M.D., vice chairman, New York, and Rema Lapouse, M.D., secretary, New York. Members of the section council are Dorothea Dolan, M.S.W., Illinois, Ernest Gruenberg, M.D., New York, Morton Kramer, Sc.D., Maryland, Benjamin Pasamanick, M.D., Ohio, and Ruth Simonson, R.N., New York.

The mental health section welcomes as members all who are interested in the epidemiological and administrative problems of mental health services for the public.

Application blanks for membership in the American Public Health Association may be obtained from the headquarters office at 1790 Broadway, New York 19, N. Y. Membership in the mental health section may be requested at the time of writing the application.

School Health Practices . . .

Find Familiar Sounds Test Best for Preschoolers

The University of Denver Hearing Center is recommending that health departments try the center's adaptation of Glorig's familiar sounds technique when they test the hearing of young children.

A pilot study, reported by the director of the hearing center, Marion P. Downs, M.A., has shown that a dog's bark, an auto horn, a telephone bell, and other familiar sounds are more readily identified by children 2 to 5 years old than are the unfamiliar tones heard in the individual pure tone sweep check.

The familiar sounds test introduces a technique which had not been attempted in the screening of hearing for diagnostic purposes until it was tried in the Denver study.

The test answers the long search for a preschool screening device by investigators concerned with the importance of full hearing during the child's formative period of language development, Downs said. The diagnostic value of the pure tones is retained by virtue of filtering each sound in significant frequency band widths.

When applied to 350 3-year-olds in the survey, the familiar sounds test found a larger percentage of medically preventive cases and was easier and faster to administer than the pure tone test, she reported. Only 18 did not cooperate. The other children responded so well that the test is recommended for case finding in the first 2 grades and among preschoolers. Screening time need take only 2 minutes for each child if orientation is given in pre-screening sessions rather than during the actual testing.

The individual pure tone sweep check is the only pure tone test which can be presently relied on for good results for kindergarten through

second grade, Downs said. It also requires a technician well trained in audiometry with children. The Massachusetts test, the Glorig audiometer, and the Reger-Newby audiometer provide fast group screening methods from the third grade on, she noted.

Now that these tests, including the familiar sounds test, offer reliability for school use at all grade levels, it remains for health departments to pursue hearing programs with proper otological and educational followup, Downs concluded.

Preschool Study

In the Denver study, a series of familiar sounds were recorded after being filtered into fairly narrow frequency band widths. For example, a dog's bark as recorded contained only the frequencies 1,000 to 2,000 cycles per second. Two sounds were recorded at the 250-750 c.p.s. band width, 2 at the 1,000-2,000 band, and 2 at the 3,000-5,000 c.p.s. band width. The band widths were considered sufficiently diagnostic for medical purposes.

The child first heard the sound at a loud level of 50 decibels. He was then asked to point to a picture representing the sound. One sound at each band width was presented to each ear. He was then told to listen while the sound was repeated at 15 db. When he failed to indicate that he could hear at any one band width, he was rechecked.

In addition, the child was also given a pure tone sweep check at 15 db. and told to raise his hand on hearing a tone. Any failure in either screening technique was later retested by a clinical threshold audiogram. On-the-spot threshold tests were given at random to 1 out of every 5 of the 350 children. Reliable responses were obtained on every retest.

Eight percent of the children were

found by the threshold tests to have significant losses of 15 db. or more. Of this 8 percent, 96 percent failed to pass the familiar sounds test whereas only 3 percent had failed the pure tone screen. The familiar sounds test missed only 4 percent of the children with significant losses while the pure tone test missed 61 percent. The incidence of unnecessary rechecks was lower for both tests than is normally expected: 5.6 percent of the children found to have normal hearing in the threshold tests did not pass the familiar sounds test as compared with 2.4 percent by the pure tone screen.

Of the 25 final failures, medical reports were obtained on 20, 14 from otologists and 6 from pediatricians. The reports confirmed the presence of ear pathologies. Eleven of the failures have received medical treatment and followup audiograms. Although the followup is still in progress, 3 have been restored to perfectly normal hearing.

A Healthful Environment Is School Child's Right

A good mental health program, healthful physical surroundings, health education in the school, and adequate health services in the school and community should all be a part of the school child's environment, according to Marie A. Hinrichs, M.D., Ph.D., director, bureau of health services, Chicago Public Schools, Chicago, Ill.

Although each has its separate part, the home, the school, and the community share responsibility for providing a healthful environment for the child, Hinrichs said. The home prepares him for his school experiences. If he has been taught respect for authority, for the dignity of work, and for the rights of others, if allowance has been made for his shortcomings, and if his failures have been accepted with understanding, it will be easier for him to move on to the larger environment of school, Hinrichs stated.

Home and School

Both home and school are working toward the development of a healthy, happy adult who will work for the creation and maintenance of a desirable community for himself and his family. To function effectively, the home and the school must work together, she said.

Parents, teachers, and administrators can all contribute toward providing a "healthful emotional climate" for the child, Hinrichs stated. A wise administrator will sponsor a curriculum of healthful living, with emphasis on day-to-day problems rather than on academic subjects, and an understanding teacher will be a child's most frequent counselor and guide.

Conferences with parents as part of the teaching plan will bring about the most effective results in health education, and joint planning in all areas will make for rapid and lasting progress, Hinrichs asserted.

Community Responsibility

The effectiveness with which parents, teachers, and school administrators present their problems to civic leaders will determine the degree of community acceptance of responsibility for health and safety, she stated.

Community responsibility for health and safety includes adequate fire and police protection; traffic control; inspection of buildings for structural stability and safety of stairs; sanitary control of community water supplies, their use, and the disposition of dissolved or suspended wastes; and supervision of garbage and refuse disposal, lighting, heating, and ventilation, Hinrichs said. The hazards of working with complex machinery and the danger connected with the use of atomic energy should be kept constantly in mind, and possible causes of accidents should be sought and removed.

Although these are community responsibilities, Hinrichs said, competent individuals in the home, the school, and the community should be

alert to detect and report any deviation from accepted standards in these areas.

In conclusion, Hinrichs said that recognition of the need for joint support of the school health program by all segments of the environment—the home, the school, and the community—will be the most effective means of promoting the health of the school child.

Norm Selection Is Important To Health of School Child

School health workers measure the growth of children to describe characteristics, to identify undesirable deviations from normal, and to select children for special study, stated Howard V. Meredith, Ph.D., professor of physical growth, State University of Iowa, Iowa City.

Care should be exercised in selecting standards, or norms, of growth, Meredith said. It is important to recognize the differences between norms for description, for appraisal, and for screening, he emphasized. School health workers should be able to turn records of height and weight into interesting information on growth and into useful aids in health appraisal.

Descriptive Norms

A descriptive norm should not be confused with norms for appraisal or evaluation, Meredith continued. For example, a norm may be constructed to describe the height status of a group of schoolboys, all of the same age, in a particular geographic area. Records of the boys' measurements are first arranged in order, from the shortest to the tallest, and then divided into categories at the 10th, 30th, 70th, and 90th percentiles.

Using these specifications, it can be determined whether a boy is tall, moderately tall, average, moderately short, or short. Such a norm is valuable for description, but it does not provide a basis for determining whether a boy is undesirably tall

or whether he is retarded in height, Meredith pointed out.

Appraisal Norms

Norms for appraisal, or evaluation, are used to determine "whether the organism is satisfactory or unsatisfactory, fit or unfit, healthy or below par," Meredith stated. Such norms are more difficult to construct than norms for description.

Before constructing appraisal norms, investigations must be made to determine the relationship between "what is valued and what is projected for normal use," Meredith stated. In connection with height, information would be needed on such points as the consistency with which a slow increase in height is associated with the onset of disease; a rapid increase with low resistance to fatigue; and an average increase with deficient diet or frequent illness or both.

Information would also be needed on the degree of association between the rate of increase in height and nutrition, endocrine function, and physical activity. Few controlled investigations of this type have been made, Meredith said.

Screening Norms

Norms for screening do not appraise but they do more than describe. "In essence, they represent the joint utilization of two or more norms for description in ways suggested by clinical experience," Meredith stated.

Clinical observations indicate that screening in terms of growth characteristics is valuable but that slow growth or slender build do not necessarily indicate poor health, he said. Body measurements are "fruitful adjuncts to the medical examination of school children," and the use of screening norms brings to the attention of school authorities children whose health deviates sufficiently from normal to justify a medical examination to determine whether their health is satisfactory or whether they need treatment.

Selecting the Norm

School health workers usually select norms constructed by others instead of constructing their own tables and charts, Meredith said. They should choose norms that will describe and screen rather than appraise and that will portray in correct perspective the growth characteristics of the pupils with whom they deal, he stated.

It is important that measurements of height and weight be carefully taken and that norms be accurate and up to date, Meredith said. In this connection, he called attention to the fact that school children today are taller by several inches than school children in 1900 and that, in girls, this more rapid development in body size has been accompanied by earlier appearance of the menarche.

In conclusion, Meredith said that norms provide the school child with a record that accompanies him from grade to grade, they furnish the health education teacher with resource material on individual variation in growth, and they bring deviations in growth status and progress to the attention of school personnel.

Suggests Economical Ways To Improve Ventilation

With an accumulating backlog of school construction and insufficient funds to meet even basic needs, Constantin P. Yaglou, M.S., professor of industrial hygiene, Harvard School of Public Health, urged that every legitimate measure be taken to cut school building and equipment costs.

Health requirements and codes for ventilating schools are not keeping pace with school construction, Yaglou said in discussing possible savings that can be made by simplified systems.

The fresh air requirements, according to Yaglou, have traditionally been based on the quantity required to dilute offensive odors to an ac-

ceptable concentration. Recent attempts to replace this criterion with one based on bacterial counts have not been completely successful. Yaglou added that no definite relation has yet been shown between sanitary ventilation based on bacterial counts and the spread of acute infectious diseases in occupied rooms, with the possible exception of measles and chickenpox.

The incidence of upper respiratory infections in Navy training station barracks was related not to the floor area or cubic space allowed per person, but to the number of persons housed in a room, Yaglou said, in recalling a World War II study. However, the study was not adequately controlled, he said, and therefore, the influence of other factors was unknown.

Problems and Suggestions

The overheating of buildings by solar heat is primarily an architectural problem, Yaglou said. He was of the opinion that the high volume of air change required for controlling solar overheating can be reduced at least 50 percent by the use of suitable overhangs and other shading devices, by substitution of heat absorbing glass for ordinary glass, and by improving distribution systems so as to handle air colder than 55° F. without causing drafts. Any rigid specification of air supply above the minimum needed for odor control is meaningless and has no place in statutory codes, he stated.

Automatic regulation of radiators and convectors is also essential to control overheating, he said, especially in rooms subjected to varying solar loads. He also favored a certain amount of variability, not exceeding 2° F. \pm , the comfort level to exact temperature controls.

Since comfort and health are affected by drafts and steep vertical temperature gradients, he recommended that the air movement be kept below 40 feet per minute and the vertical distribution of tempera-

ture be controlled at 1½° F. per foot of height in the occupied zone.

The drawback to using jacketed space heaters in rural schools, Yaglou said, was the stratification of the cold air at the floor and overheating in the breathing zone. Studies showed that New York State rural schools using this inexpensive heating method had a much higher absentee rate from respiratory illness than the city schools.

He said that either the lower cost window-gravity systems or the more expensive mechanical ventilators have shown equally good results as far as respiratory disease incidence is concerned. The positive ventilation provided by the unit ventilator in all weather conditions is its main advantage, he said, but it is higher in cost, produces fan noise and some drafts, and requires servicing of motors.

Yaglou said significant savings could be realized by finding a substitute for vent flue exhausts required by law. A less objectionable substitute is a small fan-motor unit that would exhaust the used air from individual classrooms directly to the outside through a hole cut in the wall and equipped with check louvres. Such a unit, he pointed out, can be used with mechanical or modified window-gravity supply systems without encroaching on fire regulations. Smoke, in case of fire, would be ejected at the source.

Yaglou said the recent trend toward one-story prefabricated steel schools offers good possibilities for simplified ventilating systems. Standardization and elimination of costly fire-escapes, fireproofing, stairways and stair halls, duplicate toilets and extra exits, are among the economies offered by this type of construction. Properly designed for the climate, the one-story structure is particularly adaptable to suburban residential districts, he said, but he doubted that it was the best investment for congested city districts. Other savings Yaglou cited could be effected by reduction of ceiling heights, and adaptation of a single

all-purpose room combining auditorium, playroom, and cafeteria functions in elementary schools.

State Ventilation Regulations

There are now 18 States, 1 more than in 1930, having no codes governing the heating and ventilation of public schools, he reported. Nine States have general provisions stipulating only "adequate" heating and ventilation. The remaining 22 States, 1 less than in 1930, have statutory or State board regulations specifying various requirements.

The 22 States exercising controls require a minimum fresh air supply of from 10 to 15 c.f.m., instead of 20 to 30 c.f.m. as was common in 1930, for class, study, and recitation rooms. Eight of these 22 States require that the total air supply (outside plus recirculated air) must not be less than 30 c.f.m. per pupil, a standard that Yaglou said could not be met without the use of fans.

New York regulations for heating and ventilation, as amended in 1947, are the most rational and up to date in his estimation.

New York State requires that heating systems be designed and guaranteed to maintain certain specified temperatures in different sections of the school, with a vertical gradient not exceeding 5° F. from the floor to the 60-in. level. The ventilating system must provide a minimum air change of 10 c.f.m. per pupil to remove odors without producing drafts. The air movement in zones of occupancy must not exceed 25 f.p.m.

For effective thermal operation in mild weather a design factor of 15 c.f.m. is recommended. When extensive use of a school building is anticipated in hot weather, the department may require installation of an air conditioning system or the use of electric fans. Independent ventilation systems are required where toxic substances or strong odors are produced. Authority to approve places and specifications for school buildings is vested in the commissioner of education.

Urges More Rigid Control Of School Lunchrooms

School lunchrooms should be included in the food sanitation programs of the city and county health departments in the opinion of John H. McCutchen, M.P.H., director of the bureau of food and drugs, Division of Health, Jefferson City, Mo.

Further, school lunchrooms should be issued permits and grades as any other eating or drinking establishment in the community, and violations of regulations should be dealt with in a similar manner, he said.

In Missouri, McCutchen said, the department of education reviews all school building plans before State approval is given for State aid. This does not cover all the school lunchrooms being built throughout the State, but a large percentage of plans for new lunchroom facilities come in for review in this way. McCutchen stated that in many instances defects in plans have been corrected.

One of the major problems, McCutchen stated, to be encountered is the lack of adequate space for the preparation and serving of food. Space for separate facilities has not been allocated in many existing schools. The usual result is that space now used for storage and other purposes is converted into food preparation rooms since overcrowded classrooms have taken up all other available space.

The first of two resulting problems is inadequate hot water facilities. Hot water heaters cannot be made to produce the desired hot water for rinsing dishes by simply turning up the thermostat or attaching a booster heater, McCutchen emphasized.

Every hot water heater is designed to operate at a definite B.t.u. input and the upper limit of the thermostat should not be exceeded, he explained. The recovery rate of such hot water heaters should be determined mathematically beforehand. School authorities should try to determine how much hot water will be

needed and how much space is available before proceeding with construction plans.

Cites Defects

Inadequate illumination is the second problem in McCutchen's opinion. He said it has been found that the degree of sanitation is directly proportionate to the amount of properly distributed light. Without adequate light, the lunchroom employees cannot tell when the equipment and facilities need cleaning or whether they are actually clean after being washed.

McCutchen said that these are some of the other defects in lunchroom construction plans: no specifications for kitchen equipment; grease-resistant asphalt tile not specified; inadequate space for kitchen and storeroom; no walk-in cooler, insufficient refrigeration capacity; soiled-dish window too small; no clean-dish tables; dining area too small; lack of adequate hand-washing facilities; improper location of toilet facilities; failure to provide a sneeze shield for cafeteria lines.

McCutcheon contended that the local health department and the school administrators are responsible for providing adequate space for the kitchen and dining areas, proper equipment, and proper construction. To assure proper sanitation, school administrators should consult with the health department about building plans before commencing construction.

To assist the school officials and the employees of school lunch programs, Missouri conducts food handling courses. Junior and senior classes of the high school are also invited to participate in this training course. When the students learn the proper sanitation procedures, McCutchen said, they demand them and are quick to criticize improper techniques in public establishments. Many also tell their mothers about the proper methods of handling food, cleaning, and sanitizing dishes and equipment.

School Dental Results Questioned by ADA

School health programs that fail to be reviewed periodically according to Perry J. Sandell, M.Ed., director of the bureau of dental health education, American Dental Association.

Sandell reported that in 1955 the bureau of economic research and statistics of the association sought to determine the number of cities having school dental programs and the characteristics of these programs. Completed questionnaires were received from 2,228 cities (63 percent) with populations exceeding 2,500.

Dental Personnel

Ninety-five schools (7.1 percent) had the services of a full-time dentist. In 83 percent of the cities, dentists worked part time; of these, 43 percent donated their services.

Full-time dental hygienists were employed in 22.1 percent of the reporting schools. Dental hygienists, employed on a part-time basis, were reported by 11.7 percent. Of these, about one-fourth donated their services; the others were paid by various organizations.

Services of Dentists

Mouth examination was the most frequent service. It was included in the reports of 74.1 percent of the responding cities. Annual examinations for all students were reported by 25 percent, annual examinations for certain grades only were held in 38 percent, and examinations at irregular intervals were made in 10 percent. Only 21 percent of the cities referred students to their own dentists for complete examination.

Some dental treatment was provided in 60 percent of the school systems. Fillings and extractions were provided upon request in 10 percent of the cities. In 8 percent of the cities, topical fluoride treatments were provided for certain age groups.

Services of Hygienists

Dental hygienists made annual dental inspections of all children in 13 percent of the cities, whereas in 16 percent they made annual inspections in certain grades only. In half of these schools, children were referred to their dentists for examination. Prophylaxis was provided by the dental hygienists in 18 percent of the reporting cities and the median amount of time spent was 40 percent. In 20 percent of the cities, hygienists gave topical fluoride applications and devoted 40 percent of their time to such treatment.

Educational Activities

In 27.1 percent of the cities, dentists served as consultants to teachers in their health instruction programs; in 14 percent they appeared before classes to speak on care of the teeth.

Hygienists served as consultants and aided in inservice training of teachers in 18 percent of the cities. In 20 percent, they taught dental health in the classroom, part time. Followup visits to the home were made in 18 percent of the cities.

General Observations

Unless dental inspection succeeds in determining dental health status and in motivating the child and parents toward better dental care, Sandell stated, the value of inspection is doubtful. He said reports show that dental care is lacking for many children, which indicates that dental examination alone does not guarantee dental health.

Sandell urged that procedures used in developing an inspection program and the functions of specialized personnel be analyzed carefully so that the educational potentialities can best be utilized.

Dental Health Education

Sandell commented on various approaches to dental health education, with reference to a survey of opinions and experiences of dental directors. In one instance, a director promoted a graded course of study in dental health and a parent education

program designed to stimulate interest in fluoridation. Still another suggested an X-ray survey program, comparable to that of the tuberculosis survey, with an educational program to precede and to follow the survey, as well as a followup program to bring pupils in for treatment. Some schools have begun inservice training programs for teachers. Others reported success in programs using science classes to conduct Snyder tests for dental caries susceptibility.

The parent-teacher association in one State has recognized the importance of education of the parents in dental health by establishing a study course in dental health for all local units of the association. These were developed with the assistance of the health department and the dental society.

Schools Can Aid In Fight Against Poison Mishaps

An organized attack by educational institutions on the problem of accidental poisonings has been proposed by Fred V. Hein, Ph.D., consultant in health and fitness, bureau of health education of the American Medical Association.

Schools should contribute, said Hein, to the prevention of such accidents through the following: (a) use of existing adult education channels, including home-school organizations such as parent-teacher associations; (b) emphasis on preventive procedures throughout the school careers of children and youth; (c) stressing such measures in high school and college courses relating to the education of prospective parents.

Institutes, classes, study groups, meetings, forums, and conferences for adults on many subjects might appropriately include information on poisoning hazards and prevention, he said. The same applies to educational radio and television, newspaper articles, periodicals, and bulletins to homes.

More than 30 million children alerted in school to poisoning dangers might function as salesmen for safety, Hein stated. In the lower grades such training could be given to children in the form of simple "do and don't" instruction integrated with regular activities of the school day. As children gain understanding they might be taught the "how and why" of safe practices with regard to the handling of potentially poisonous substances. Hein pointed to the many opportunities for teaching of accidental poisoning prevention along with other subject areas in the secondary school curriculum, such as

classes in health, industrial and fine arts, science, and homemaking.

Prospective parents have often been neglected in educational efforts designed to enlist the cooperation of families. Yet many secondary school and college students will become parents in the near future. When they have actually become parents, only a portion of them can be reached, and then only indirectly, Hein stated, concluding that it was especially important that these older students be made aware of accidental poisoning hazards and of opportunities for taking adequate safety measures.

promotion of a better dental program.

4. To encourage the observance of proper dental health practices including personal care, professional care, proper diet, and oral habits.

5. To encourage better patient-dentist relationships.

6. To present how the dental health activities may be correlated with the public health program.

7. To educate the public to the value of adequate dental care for children and youths and to develop the resources that make such programs possible.

8. To continue to promote better education programs in colleges and universities for prospective teachers of health education.

9. To encourage and emphasize the need of public health courses for the undergraduate dental students so they might be better prepared to participate in their community's dental program.

10. To interpret the dental program to the practicing dentists and stimulate their interest and responsibility.

Dental Care and Services . . .

Long-Term Dental Health Via 10 Short-Term Goals

Too few parents consider the condition of the child's teeth until he is ready to enter school and then usually as a result of the dental educational feature of the summer roundup program, remarked William A. Jordan, D.D.S., M.P.H., chief, section of dental health, Minnesota Department of Health, Minneapolis.

Overcoming this indifference in ourselves as individuals and as parents, stimulating the leadership of the dental profession in their own segment of health education, and sparking the interest of legislatures in the reasons for good dental health are the major foci of dental health education, Jordan continued.

The family dentist misses many opportunities to contribute to dental education, Jordan believes. When he says to his patient, "Sugar causes tooth decay," that is the occasion to describe how decay is created through the process of oral bacteria feeding on sugars in the mouth, producing an acid which attacks the

tooth enamel. It is an opportunity for him to tell how fluorides ingested or topically applied can create resistant tooth enamel.

Too often, particularly with fluoridation programs, the opposition has done a better job than the proponents, Jordan observed.

Short-Term Objectives

Jordan listed short-term objectives which he feels are within the realm of achievement, and added that of the methods for attaining them the most needed are undergraduate public health courses established in all schools of dentistry; courses in dental health required for public health nurses; and improvements in health education material presented to undergraduate teachers. His list of objectives included the following:

1. To teach every individual the importance of keeping his mouth healthy throughout his lifetime.

2. To understand the important relationship of dental health to general health, outward appearance, and even mental reactions.

3. To relate the services available from all groups and agencies in the

Can Extend Dental Services With Auxiliary Personnel

Because of the shortage of dentists, a realistic staffing plan for dental public health programs should depend on auxiliary personnel to extend services, according to Norman F. Gerrie, D.D.S., M.P.H., acting chief dental officer of the Public Health Service.

Many dental health program functions can be performed by available auxiliary personnel such as dental hygienists, health educators, and public health administrators, he asserted.

The demands on the public health dentist have increased with the growth of technical and administrative knowledge in the field so that the dental public health administrator is pressed to keep up with his work, Gerrie declared.

It is his responsibility to plan the dental program, and to integrate and coordinate it with the other activities of the health department, he said. He should be designating and defining dental needs of the community, selecting objectives and assigning priorities, working with dental organizations of the area, and making sure that the quality of the work in the dental program earns public respect and appreciation. In this task few dental administrators can hope to have public health dentists as assistants, he said.

This, he explained, is because: (a) the national supply of dentists is known to be inadequate; (b) since dental public health has achieved specialty status, expensive training after regular training is required; (c) dental schools orient their students for private practice, which is much more lucrative than public health dentistry; and (d) the demand for public health dentists has risen steadily since 1918.

Suggested Criteria

In the past, auxiliary personnel were selected because they were more readily available and less expensive than dentists, were already in the field, or were trained in fields which enabled them to bring to the dental program skills of potential value. Such personnel were employed with varying degrees of success, he commented.

Useful criteria for choosing auxiliary dental personnel, Gerrie suggested, are that the individuals considered should: (a) have adequate basic preparation for the job; (b) have public health training, either a year in a public health school or integrated training during the basic preparation; (c) be available in adequate numbers or such availability promised; and (d) be acceptable to the public in their job capacities.

These criteria, he declared, point to health educators, dental hygienists, and public health administrators as acceptable auxiliary personnel.

The Three Groups

Health educators bring skills particularly valuable in dental education programs and in the use of printed materials, in working with community organizations, in conducting workshops and inservice training programs, he said.

The adequately trained dental hygienist with a degree is more useful to the program than is the 2-year hygienist trained primarily in clinical operations, Gerrie noted. Hygienists have been employed for lectures to students, teachers, and parents and could conduct surveys for the dental administrator. They can give classes in dental health for teachers and nurses. In community planning, the hygienist could coordinate action with the health educator; each may act as a resource person for the other. The hygienist can double for the dentist except in activities involving technical interpretation.

The public health administrator brings to his job knowledge of public health philosophy, techniques, methods, and related elements of all public health disciplines. He can contribute to planning and evaluation. He could develop procedures for surveys and prepare preliminary drafts for the required administrative reports.

Research Needed

Auxiliary workers with other skills may be used as new needs arise. Research is required to identify such skills and a knowledge on the best methods of training personnel. A willingness to try to discover the best uses of auxiliaries may lead to a significant easing of the shortage of manpower in the field, Gerrie asserted.

Long-Term Dental Survey Advantages Reported

A long-term study of dental caries incidence and periodontal disease in Prince Georges and Montgomery Counties, Md., has provided findings

which could not be obtained from a cross-section survey, according to A. L. Russell, D.D.S., M.P.H., of the National Institute of Dental Research, National Institutes of Health, Public Health Service, Bethesda, Md.

The long-term procedure yields information which can be elicited by no other techniques, he said. "A principal advantage of the method is that any observation can be analyzed as a mean change and hence is amenable to any desired dissection by statistical analysis. The uncertainties of dealing blindly with absolute values are avoided."

Some of the types of data which are accessible only through long-term examinations were illustrated in the findings of the chronic oral disease investigation in Maryland. These types were: the direct estimation of incidence, increment over a given time span, with known error components; the relationship between two effects which are observed rather than assumed to coexist through the period of study; and the retrospective study of persons in whom a given effect appears, compared with similar persons in whom the effect did not appear, based directly on data of record.

The Maryland Study

The study began in 1951 when the National Institute of Dental Research was invited to participate with the Southern District Dental Society of Maryland in a prefluoridation survey of dental caries. A long-term study was conducted in which 5,000 to 6,000 elementary and junior high school students were examined during the same calendar week each year, Russell said.

A method was devised for scoring periodontal disease from zero to 8.0 with the higher scores indicating more severe damage. The mean numbers of decayed, missing, or filled permanent teeth permitted scoring over a continuous scale for dental caries.

Comparison of caries activity and gingival status for the observation period revealed a tendency toward

increasing caries activity with increasing gingival inflammation for children with only simple gingivitis. There was an unusually large number of children with clean mouths in 1955 who had shown simple gingivitis in 1954. About 8 out of 9 with such reversals exhibited objective evidence of professional care during the study period. Such care had been received by only about 2 children out of three for the entire group.

Children receiving care during the year or showing no need for care at the beginning and end of that period showed a very low prevalence of gingivitis, according to Russell. Definitely more gingivitis was seen in a small group which received only emergency treatment. The remaining children who did not receive care

were grouped into three categories roughly representing the degree of neglect of care.

In this grouping, children whose care needs had been met at the outset of the period, but who had not yet received treatment for lesions appearing during the year, showed the least gingivitis. Intermediate were those in whom generally small carious lesions, present at the beginning of the year, received no treatment during the 12 months. Children who exhibited gross neglect had the most gingivitis.

Russell pointed out that the long-term survey is not the method of choice in studies where the data required may be obtained directly through a single cross-section survey.

His co-workers believe that the method warrants further study from the standpoints of both theory and practical application. Few physicians are willing to take part in morbidity studies, they said, and those who are available usually require a period of orientation to population studies, whereas interviewers can be found in any community and can be trained by the study staff. Use of interviewers for these studies is much less costly than the use of physicians, and many more persons will reply to an interviewer's questions than will undergo physical examination by a physician, Rubin and his co-workers said. It is their feeling that the most important gain from this technique is the increased response rate.

Epidemiology . . .

Nonmedical Interviewers In Morbidity Surveys

Techniques are needed by which morbidity surveys of the general population may be used by the epidemiologist to study associations in noncommunicable disease which are worthy of further investigation, stated Theodore Rubin, Ph.D., Joseph Rosenbaum, A.B., and Sidney Cobb, M.D., M.P.H.

Dr. Rubin is research associate in epidemiology and Dr. Cobb is associate professor of epidemiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, Pa. Mr. Rosenbaum was a research associate in epidemiology at the University but is now with the Rand Corporation in Santa Monica, Calif.

Clinical impressions are usually the basis for hypotheses about diseases, but clinical impressions are obtained from a biased population, and a way is needed to check these impressions in representative popu-

lation studies, Rubin and his co-workers said.

The use of the nonmedical interviewer as an alternative to mass screening techniques or clinical examinations is suggested as having the advantages of a high response rate, low cost, and an available staff to compensate somewhat for the lack of diagnostic accuracy.

The substitution of "virtual" classifications of disease obtained by nonmedical interviewers for the "true" classifications obtained by clinical examination by physicians presents certain limitations also. Rubin and his co-workers discussed these limitations and offered a formula for selecting a sample population and a set of questions that might be used, in lieu of clinical methods, to detect associations with rheumatoid arthritis.

Further Study Warranted

Despite the limitations imposed by the substitution of virtual for true classifications of disease, Rubin and

Insured Groups Valuable In Genetic Studies

Enrollees of prepaid medical care plans provide an excellent medium for research into genetic and epidemiological problems of clinical medicine, according to Louis E. Schaefer, M.D., and David Adlersberg, M.D.

The contributions that such programs could make to genetic and epidemiological research "may eventually represent, quite apart from the socioeconomic value of prepaid comprehensive care on a group basis, significant and valid reasons for the existence of such planning," they said.

Dr. Schaefer is associate medical director, Central Manhattan Medical Group, and research assistant in medicine, Mt. Sinai Hospital, and Dr. Adlersberg is associate attending physician for metabolic diseases, Mt. Sinai Hospital, New York, N. Y.

Groups for the study of clinical genetics in man are much in demand, and population material must be readily available if genetic problems are to be worked out directly, they said. By using enrollees of prepaid medical care plans, entire families can be examined, pedigrees

can be established, and twins can be studied, they stated.

Pedigree Method

Medical care plans, such as the Health Insurance Plan of Greater New York, enroll and provide medical care for families—parents and all children up to 18 years of age—as a unit, Schaefer and Adlersberg stated. In groups such as this, “an entire segment of a virtually unselected population can be investigated for the occurrence of an inherited trait,” and studies can be repeated in a relatively stable population, they pointed out.

Furthermore, laboratory and clinical studies can be made within the framework of the subscriber's ordinary relationship with his physicians, and complete records of the entire family are available in the offices of the medical group. An added advantage has been the cooperativeness of relatives of the families in the study group, who often must be questioned and examined to complete the research, they stated.

Staten Island Studies

Schaefer and Adlersberg reported that studies of the genetic mechanisms in idiopathic cholesteremia are being made in families enrolled in the Staten Island medical group of HIP. Previous studies of this condition had been carried out in a hospital, but it was felt that investigations of a metabolic disorder of this type, which occurs in individuals who appear to be healthy otherwise, should be made in family groups representative of the general population.

Epidemiological studies of cholesterol levels have been conducted simultaneously with the genetic studies, they said. Findings indicate that the rapid increase in average cholesterol levels in men, beginning at age 20, produce changes which may result in the high frequency of coronary disease in the earlier decades of life; and that the same phenomenon begins 13 years later in women and continues 12 years longer than it does in men.

A longitudinal study of men and women whose cholesterol levels have been carefully observed through the critical decades will be required to prove this hypothesis, they stated, and the families in the HIP-insured group will be particularly suitable for such a study.

In conclusion, Schaefer and Adlersberg said that the Staten Island studies demonstrate the integration of genetic and epidemiological research with the clinical practice of medicine, using techniques employed by the internist in his daily practice, with no exploitation of or inconvenience to the patient, and that these studies will be continued and broadened.

Study Accents Value Of Early Diagnosis

Recent New York State studies confirm that a great gain in survivorship of cancer patients will probably

result if cancer cases are diagnosed in the early, localized stage.

This opinion was expressed by Arthur S. Kraus, M.S., associate biostatistician, Morton L. Levin, M.D., assistant commissioner for medical services, Rita E. Cashman, M.S., biostatistician, and Paul R. Gerhardt, M.D., director of the bureau of cancer control, New York State Department of Health, Albany, N. Y. They reported results of a study of 2,065 cases of cancer with known or reported onset during 1940–42, found in 6 counties of northern New York State during the period 1940–47.

The 5-year survival rate for the cases in the study was 27.7 percent, Kraus and his associates reported. Survivorship was determined for single years up to 5 years after onset. Patients were classified as dead in 1 of the first 5 years following the onset of cancer, alive 5 years after onset, or lost to observation while alive in one of the first 5 years after onset. The probability of dying from cancer during a given year decreased

Survival rates of study group and general population.

in each successive year, from an annual rate of about 30 percent in the first year after onset to about 16 percent in the fifth year.

Site and Age

Survival rates for cancer of the skin were higher than for cancer of any other site, Kraus and his co-workers said. The major sexual sites, followed by the major non-sexual sites, had the next highest rates of survival. Leukemia had the lowest survivorship rates of all major sites. The rate of survivorship for the six internal sites common to both sexes was higher for males than for females. The adjusted survival rates showed some difference in time trend for different sites.

The survivorship of all cancer cases of each sex was higher in the under-55 age group than in the older group, the investigators reported. This relationship was statistically significant for uterine cervix cancer in women under 35 and for ovarian cancer in women under 45, they said. While part of this relationship appeared to be explained by the tendency of younger cases to be diagnosed at an earlier stage of disease than older cases, factors other than stage

of disease at diagnosis appear to be involved. The study also showed that inclusion of a higher proportion of false positive cases among the younger group did not account for the higher survival rate of the younger group.

Stage at Diagnosis

Persons of both sexes whose cancers were diagnosed in the early, localized stage had a higher survival rate than persons diagnosed in other and unstated stages. This finding was most striking for the sites with the lowest survival rates—ovary, bladder, large intestine, and rectum. The higher survivorship rate for patients with cancers diagnosed in the early, localized stage was not due to the inclusion of a higher proportion of false positives among this group.

Kraus and his co-workers concluded that the results of this study represent the minimum survivorship for the diagnosed cancer population of the six counties studied. They believe that, except for the factor of chance fluctuation, these results are approximately representative of the situation for the period studied in the entire State of New York, exclusive of New York City.

phases of the test. He designated the serum tested another variable.

The standardization of hemolysin and complement may be accomplished by checkerboard titration, and optimal dilutions obtained. Another procedure is the titration of hemolysin in the presence of a constant dilution of complement and subsequent titration of the complement in the presence of two units of hemolysin, he said.

"Several laboratories have streamlined the complement fixation test to accommodate the testing of large numbers of serums with several antigens by using a single dilution of complement for the entire battery of antigens. In this procedure, the amount of complement used for each antigen ranges from 1.5 to 2.0 units for each antigen instead of 2.0 exact units," he said, warning that such a system is hazardous unless controlled.

He recommended the restandardization of each lot of commercially procured antigen. Antigens may be titrated by the checkerboard or straight line pattern. In the latter case, serial dilutions of antigens are tested with a single dilution of homologous immune serum. If the titer of the reference serum is of too low a value, the antigen may not detect low levels of antibodies in a patient's serum.

The force maintained in centrifugation of the sheep red-blood cells may influence the sensitivity of the test. Bernstein advocated that directions for the application of centrifugal force in preparing cell suspensions be given in terms of gravitational units rather than the more commonly supplied revolutions per minute.

Also, he called attention to a process whereby centrifugation of cell suspensions for maximum cellular packing is unnecessary. With reference to the true hematocrit value for a portion of a washed-cell suspension, determined with a Bourke-Enstine hematocrit tube, and the volume of the stock suspension, a dilution may be prepared for the desired concentration. Suspensions

The Virus Diseases . . .

Complement Fixation Tests Need Standard Procedure

An evaluation of the various techniques used in the virus complement fixation test and the development of a standard procedure acceptable to all laboratories is needed, according to Alan Bernstein, Ph.D., acting in charge of the Reference Diagnostic Unit of the Communicable Disease Center, Public Health Service, Montgomery, Ala.

There are probably as many techniques as there are virus diagnostic laboratories, he said. This situation does not permit laboratories to handle maximum loads or compare results among themselves.

Five Variables

To illustrate his thesis, Bernstein referred to the standardizations of antigen, complement, and hemolysin and the preparation of constant concentrations of sheep red-blood cells suitable for this purpose as variable

prepared in this way may be more accurately reproduced than others.

Incubation of specimens for only 1 or 2 hours at 37° C. provides for a less sensitive but quicker and more specific test than overnight incubation in the cold. Although the former process may be resorted to in an emergency test, Bernstein advised that, for specimens thus found negative, the test be repeated with an overnight incubation period.

Special Problems

The supply of positive serum for control purposes is more limited than that of any other necessary reagent, he said. Human serum is more desirable than animal immune serum, but even commercial stocks of animal serum are small. However, Bernstein held that through cooperation among virus diagnostic laboratories in different areas where different virus diseases are prevalent sufficient quantities of all types of human serum might be made available to all laboratories at little expense. For example, southern State laboratories could exchange typhus serum for lymphocytic choriomeningitis serums with the laboratories in the Middle Atlantic and New England States.

Concerning the interpretation of test results, he listed three possible complicating factors: haphazard collection of serum specimens; lack of ample clinical data on patients; and the occurrence of nonspecific reactions.

"Ideally, the first serum specimen should be obtained within the first few days after clinical onset and a convalescent specimen obtained 2 to 4 weeks later," he said. "The specimens should be submitted with a proper history that indicates date of onset and collection of specimens, a summary of the clinical symptoms, and the physician's provisional diagnosis. Information concerning vaccinations, recent travel, and intimate contact with animals or individuals with similar symptoms is as important as the clinical symptoms in aiding in the interpretations of results."

Problems of nonspecific reactions arise more frequently with antigens prepared from embryonated eggs than those prepared from mouse or guinea pig tissues. If necessary, he said, serums may be treated with normal embryonated egg membranes to remove a nonspecific antibody, or absorbed with packed sheep cell suspension if the antibody is of the heterophile type.

While the serums of some patients, especially those with positive syphilis serologies, are inherently anticomplementary, bacterial or chemical contamination of a serum may also cause anticomplementary reactions. Reactions of this nature may occasionally be attributed to excess amounts of oxalate, citrate, heparin, or merthiolate. Improper storage and handling of the antigens may result in anticomplementary reactions or deterioration of the activity.

"It is important, therefore," he insisted, "that every test include not only antigen and serum anticomplementary controls, but also a positive serum control, so that the potency of the antigen be known." Inclusion of normal antigen controls will indicate the presence of nonspecific reactions.

Bernstein mentioned several problems involving specific viruses or groups of agents. A history of recent vaccination, he said, may complicate diagnosis of influenza by complement fixation test and may be a problem in future serologic diagnoses of poliomyelitis. Again, the extensive use of broad spectrum antibiotics has resulted in a special problem in the diagnosis of infections by the rickettsiae and psittacosis-lymphogranuloma venereum group of viruses.

Lead Fight on Viruses, Health Officers Told

With communicable diseases fading as the major public health concern, the health officer should lead in the fight against the "hard core" of

communicable viral infections, stated John E. Gordon, M.D., professor of preventive medicine and epidemiology, Harvard University School of Public Health.

In addition to applying the principles of communicable disease control and acquiring familiarity with characteristics of already known viruses, the health officer should contribute to new knowledge through field studies of virus diseases, he said.

Virus diseases include the most common, most dangerous, most curious, most obscure, and the main part of the newly discovered diseases, but, "to complicate matters, as virologists have expressed it, there are newly discovered viruses seeking a disease as well as the more orthodox situation of a disease looking for its viral agent," Gordon said.

As the practice of preventive medicine enlarges and as the composition of populations changes, neoplastic and degenerative diseases, mental disorders, and traumatic injury are properly incorporated into public health programs. Gains in the control of communicable diseases often permit more effort in these other fields. But, he said, judged by disabilities, deaths, and their contribution toward other conditions, the communicable diseases remain the backlog of the public health program.

Local Health Officers

The local health officer has the main responsibility for communicable disease control. For virus diseases, as with all others, the measures put into practice depend upon information gained through practical field study of the particular situation, Gordon declared. Local health officers and physicians must know which viruses can be diagnosed in the laboratory and which cannot. They must also know the kind of material to collect for the laboratory and how to collect and forward such materials.

State Health Officers

The State health officer should help by offering consultation and

by providing diagnostic laboratory facilities and skilled workers. As laboratories are costly and qualified workers are few, facilities are ordinarily provided by the State, or by arrangement with 1 of the 30 cooperating laboratories of the Public Health Service, he noted.

The State health officer should see that all physicians and local health officers have all the necessary information on virus diseases, Gordon declared. The preferred means for providing this information are short courses or conferences throughout the State, with distribution of an outline of the essential material. Alternatively, the outline and a letter may be used.

Practical Needs

Reporting of epidemics as contrasted with routine individual case reports is especially important for viral infections of irregular occurrence and for ill-defined disease of possible viral origin. Such reporting, he said, should give the number of cases, within what time, approximate population involved, and apparent mode of spread.

Existing knowledge may well be applied toward a more reasonable practice of isolation in respect to a number of the more common virus diseases, he commented. The evaluation of control procedures requires more emphasis than commonly accorded that important feature. Ipsen's procedure for bacterial diseases, whereby serologic epidemiology was a measure of extent of use and past performance of an immunizing agent and in direction of future effort, has possibilities for viral immunizing agents, Gordon said.

Army Data on Viruses

Data on the communicable diseases in World War II, just becoming available, show that 23.3 percent of reported cases of specific infectious and parasitic diseases were caused by viruses, Gordon said. If viral, presumably viral, and common respiratory diseases are placed in relation to all communicable disease,

the proportion of viral disease to the whole approximates two-thirds, he declared.

The military services have the most complete data on morbidity and permanent disability, he asserted. Communicable disease accounted for about half of all disease in Army troops during the war. Deaths from disease were only 5.1 percent of the total, 75.2 percent were battle casualties and 19.7 percent were nonbattle injuries. Disabilities, however, were 85 percent due to disease, the remaining 15 percent distributed between battle and nonbattle categories. Man-days lost were 285,918,000 from disease, 59,863,000 from injuries, and 72,000,000 from battle casualties, he reported.

The Army data are informative because they present evaluation of the communicable diseases in terms of death, defect, and disability. Judgment is too often on the sole criterion of death, Gordon asserted.

These Army data, representing American experience in most parts of the world, demonstrate that the communicable diseases are not outmoded, he said. Half of the world population lives in countries where communicable diseases rank first among causes of death. The infectious and parasitic diseases were $2\frac{1}{2}$ times as frequent among American troops in the China-Burma-India theater as in troops in the United States. Control measures evaluated on experience in the United States are not always so effective in other parts of the world, even when applied to an American population by American physicians, he commented.

Specific control measures for smallpox, infectious hepatitis, poliomyelitis, and rabies were discussed by Gordon. Rubella and chickenpox were mentioned as virus diseases for which there is no practical control under present methods. The control of infectious mononucleosis, keratoconjunctivitis, and a number of other infections of presumed viral origin is within the province of research rather than practice, he said.

Find New Virus Group In Healthy Children

The new types of enteric viruses discovered in 1953 in a study of healthy children in Cincinnati, Ohio, have since been found in even larger numbers in healthy Mexican children, according to a report by Manuel Ramos-Alvarez, M.D., and Albert B. Sabin, M.D., respectively, research associate and professor of research pediatrics, Children's Hospital Research Foundation, University of Cincinnati College of Medicine. The existence of these new viruses was revealed by the use of monkey kidney tissue cultures.

Among 1,491 children aged 1 to 4 years in Mexico City, nonpoliomyelitis viruses were found in 15.6 percent; among 280 children of the same ages in Veracruz, they were found in 10.0 percent, they specified. The comparative figure for the Cincinnati children was 5.2 percent. All the children studied were from low economic groups.

A total of 261 nonpoliomyelitis virus strains, they reported, were recovered from the Mexican children, about 65 percent of which still remain unclassified. Of 26 nonpoliomyelitis strains recovered from the Cincinnati children, 25 were found to belong to five distinct antigenic types which differ from previously known viruses, and 1 proved to be a Coxsackie B4 virus. Four of the five Cincinnati prototype viruses (2, 3, 4, and 5) were found in the Mexico City children, and one (type 5), in the Veracruz children.

Role in Disease

The significance of these new viruses in the etiology of human disease is still a problem for research, the scientists pointed out. However, they declared, it is clear that they are not the viral counterpart of the normal bacterial flora of the human enteric tract because they are found more frequently during the early years of life and, at least in Cincinnati, are found only rarely in children over 10 years of age. (Of 837

Cincinnati children 10 to 17 years old, the viruses were found in only 0.2 percent.)

In preliminary serologic surveys among Cincinnatians, neutralizing antibodies for the Cincinnati viruses were found much more frequently among those aged 20 to 30 years than among those aged 1 to 5 years, Ramos-Alvarez and Sabin reported. However, only 3 percent of the older group had antibodies against all 5 types.

The following observations, they said, suggest that at least some of the new viruses may prove to be related to infections of both the respiratory and enteric tracts: A virus associated with an epidemic of rhinitis in chimpanzees and another associated with a family outbreak of an acute "steatorrheic" enteritis were found to be antigenically related to, though not identical with, the Cincinnati type 4 virus.

Another clue for further investigation is the finding by J. L. Melnick and his associates that some of the "orphan" viruses recovered from stools of patients with a diagnosis of either nonparalytic poliomyelitis or the aseptic meningitis syndrome were identical with the Cincinnati types 1 and 3 viruses.

Characteristics of the Viruses

Ramos-Alvarez and Sabin gave the following additional information about the five Cincinnati prototype viruses:

Types 1, 2, 3, and 5 produce in cynomolgus monkey kidney tissue cultures cytopathogenic effects which are indistinguishable from those exhibited by the poliomyelitis viruses. Type 4 produces a cytopathogenic effect distinct from the effects produced by the others and from those produced by the poliomyelitis, herpes, and mumps viruses: A clumpy degeneration of the cells appears after an incubation period of 2 to 10 days. Only type 4 virus was capable of producing a cytopathogenic effect in cultures of kidneys derived from *Cebus capucinus* monkeys.

According to Dr. Irving Gordon and Dr. William Jordan, the five

Cincinnati viruses can be propagated in HeLa cells, although the yield of virus is low.

Dr. Robert Huebner has reported that these viruses do not belong to the APC group, and Dr. Robert N. Hull states that they are distinct from the cytopathogenic agents that he recovered from normal monkeys.

Human gamma globulin was found to contain antibody for all but type 2, and antibodies for type 2 have been demonstrated in individual human serums.

The Cincinnati viruses are not pathogenic for either suckling or adult mice by the intracerebral or spinal routes. They are not pathogenic for rabbits by the intracutaneous, intramuscular, or intravenous routes. Types 1, 2, and 3 are not pathogenic for cynomolgus monkeys by the spinal route, but antibody develops as a result of the inoculation.

Virus Induced Cancers Tied to Virus Theory

No cancer has ever been induced in an animal or a medium known for certain to be free of viruses, asserted Francisco Duran-Reynals, M.D., in an exposition of the so-called virus theory of cancer. Dr. Duran-Reynals is lecturer and research associate, department of microbiology, Yale University School of Medicine.

Furthermore, he stated, a large number of cancers, especially in birds and mice, are induced by agents fulfilling all the requirements of viruses. Here the word "theory" with "virus" is unwarranted; it should be reserved for cancer in man and others of unknown etiology, he said.

The more we study viruses, the more we learn that they are present in tissues and culture media, often in an incomplete, noninfective state, he continued. He pointed out analogies between this situation and the "spontaneous" alterations or putrefaction of imperfectly sterilized media in Pasteur's time.

However, even if someday cancer is induced in animals in the proved absence of viruses, this will not change the fact that avian, murine, and other cancers are virus induced, he noted. It would mean that we have two types of cancer: infectious cancers and noninfectious cancers.

The virus theory, according to the speaker, holds that a cell invaded by certain viruses is induced to multiply at the same time that the viruses themselves multiply, an exogenous process. The only other view concerning the cause of cancer, the noninfectious view, contends that a sudden change leads to unrestricted cell multiplication even after withdrawal of the stimulus, an endogenous process.

The latter view is consistent with orthodox knowledge in histology, immunology, endocrinology, genetics, and other fields. However, since heredity, hormonal functions, and still other factors play a decisive part in making possible the effect of the virus, the knowledge accumulated in these fields is not only compatible with the virus theory also, but is indispensable for a full understanding of the virus realities, he stated.

The Age Factor

In discussing the mechanism of induction of cancer by viruses, Duran-Reynals noted that the age factor is present in the following three events:

Necrosis or stimulation of the infected cells. Observations on viruses of either cancers or proliferative processes show that cell destruction occurs in the immature host, whereas tumor formation takes place in the mature host.

Infection itself. Avian tumors—the Rous sarcoma, for example—are able to infect other species—ducks, for example—only when the latter are inoculated during immaturity.

Variability of the virus in the aging host. In the Rous sarcoma chicken-duck sequence, infection of the immature host is followed by a long period of latency or incubation;

by providing diagnostic laboratory facilities and skilled workers. As laboratories are costly and qualified workers are few, facilities are ordinarily provided by the State, or by arrangement with 1 of the 30 cooperating laboratories of the Public Health Service, he noted.

The State health officer should see that all physicians and local health officers have all the necessary information on virus diseases, Gordon declared. The preferred means for providing this information are short courses or conferences throughout the State, with distribution of an outline of the essential material. Alternatively, the outline and a letter may be used.

Practical Needs

Reporting of epidemics as contrasted with routine individual case reports is especially important for viral infections of irregular occurrence and for ill-defined disease of possible viral origin. Such reporting, he said, should give the number of cases, within what time, approximate population involved, and apparent mode of spread.

Existing knowledge may well be applied toward a more reasonable practice of isolation in respect to a number of the more common virus diseases, he commended. The evaluation of control procedures requires more emphasis than commonly accorded that important feature. Ipsen's procedure for bacterial diseases, whereby serologic epidemiology was a measure of extent of use and past performance of an immunizing agent and in direction of future effort, has possibilities for viral immunizing agents, Gordon said.

Army Data on Viruses

Data on the communicable diseases in World War II, just becoming available, show that 23.3 percent of reported cases of specific infectious and parasitic diseases were caused by viruses, Gordon said. If viral, presumably viral, and common respiratory diseases are placed in relation to all communicable disease,

the proportion of viral disease to the whole approximates two-thirds, he declared.

The military services have the most complete data on morbidity and permanent disability, he asserted. Communicable disease accounted for about half of all disease in Army troops during the war. Deaths from disease were only 5.1 percent of the total, 75.2 percent were battle casualties and 19.7 percent were nonbattle injuries. Disabilities, however, were 85 percent due to disease, the remaining 15 percent distributed between battle and nonbattle categories. Man-days lost were 285,918,000 from disease, 59,863,000 from injuries, and 72,000,000 from battle casualties, he reported.

The Army data are informative because they present evaluation of the communicable diseases in terms of death, defect, and disability. Judgment is too often on the sole criterion of death, Gordon asserted.

These Army data, representing American experience in most parts of the world, demonstrate that the communicable diseases are not outmoded, he said. Half of the world population lives in countries where communicable diseases rank first among causes of death. The infectious and parasitic diseases were $2\frac{1}{2}$ times as frequent among American troops in the China-Burma-India theater as in troops in the United States. Control measures evaluated on experience in the United States are not always so effective in other parts of the world, even when applied to an American population by American physicians, he commented.

Specific control measures for smallpox, infectious hepatitis, poliomyelitis, and rabies were discussed by Gordon. Rubella and chickenpox were mentioned as virus diseases for which there is no practical control under present methods. The control of infectious mononucleosis, keratoconjunctivitis, and a number of other infections of presumed viral origin is within the province of research rather than practice, he said.

Find New Virus Group In Healthy Children

The new types of enteric viruses discovered in 1953 in a study of healthy children in Cincinnati, Ohio, have since been found in even larger numbers in healthy Mexican children, according to a report by Manuel Ramos-Alvarez, M.D., and Albert B. Sabin, M.D., respectively, research associate and professor of research pediatrics, Children's Hospital Research Foundation, University of Cincinnati College of Medicine. The existence of these new viruses was revealed by the use of monkey kidney tissue cultures.

Among 1,491 children aged 1 to 4 years in Mexico City, nonpoliomyelitis viruses were found in 15.6 percent; among 280 children of the same ages in Veracruz, they were found in 10.0 percent, they specified. The comparative figure for the Cincinnati children was 5.2 percent. All the children studied were from low economic groups.

A total of 261 nonpoliomyelitis virus strains, they reported, were recovered from the Mexican children, about 65 percent of which still remain unclassified. Of 26 nonpoliomyelitis strains recovered from the Cincinnati children, 25 were found to belong to five distinct antigenic types which differ from previously known viruses, and 1 proved to be a Cocksackie B4 virus. Four of the five Cincinnati prototype viruses (2, 3, 4, and 5) were found in the Mexico City children, and one (type 5), in the Veracruz children.

Role in Disease

The significance of these new viruses in the etiology of human disease is still a problem for research, the scientists pointed out. However, they declared, it is clear that they are not the viral counterpart of the normal bacterial flora of the human enteric tract because they are found more frequently during the early years of life and, at least in Cincinnati, are found only rarely in children over 10 years of age. (Of 837

Q. Will the vaccine ever be 100-percent effective? A. We can have 100-percent effectiveness to the extent that lots of vaccine are consistent and resemble our "standard reference vaccine." We shall have vaccine approaching 100-percent effectiveness.

Questions which the panel did not have time to answer were referred by Dr. Merrill to Dr. Van Riper for collation. He promised to publish the answers to representative questions.

tacts of vaccinated individuals, and 20 among community contacts of vaccinated individuals.

In May 1955 safety standards and clearance procedures for poliomyelitis vaccine were revised. No epidemiological evidence has come to light that tends to render suspect any lot of vaccine of any manufacturer cleared under these revised safety standards, Langmuir stated.

Preliminary reports are now avail-

able from 11 States and 1 city on the effectiveness of poliomyelitis vaccine as used in the United States in 1955. These reports showed that rates for paralytic poliomyelitis were one-half to one-fifth as great among vaccinated children as rates among unvaccinated children of the same age.

In an attempt to find an independent confirmation of this trend in favor of the vaccine, data on the age distribution of all cases of poliomy-

Paralytic and nonparalytic poliomyelitis rates, 1952 and 1955.

Polio Surveillance Unit Finds Vaccine Effective

An epidemiological evaluation of the safety and effectiveness of poliomyelitis vaccine was described by Alexander D. Langmuir, M.D., chief, Epidemiology Branch, Communicable Disease Center, Public Health Service, in collaboration with Neal Nathanson, M.D., and Wm. Jackson Hall, Ph.D., chief and statistician, respectively, of the Poliomyelitis Surveillance Unit. This evaluation was based on the surveillance activities of the Communicable Disease Center.

The surveillance of poliomyelitis is one of the several parts of the Poliomyelitis Program of the Public Health Service. The others include the licensing of production and clearance of vaccines and the administration of grant-in-aid funds and of the voluntary interstate program for vaccine distribution.

Since April 1955, the Poliomyelitis Surveillance Unit has acted as a clearinghouse for reports provided by the States and Territories, more than 40 participating laboratories, the National Foundation for Infantile Paralysis, and other sources of current data on poliomyelitis.

Langmuir also reported that the surveillance unit had received complete data on 204 cases occurring in association with vaccine produced by Cutter Laboratories. Of these 204 cases, 79 occurred among vaccinated individuals, 105 among family con-

then a tumor, always different from the original Rous sarcoma, develops. Usually, this cancer is no longer a chicken tumor but is a duck tumor, growing in older ducks as the origi-

nal Rous sarcoma grows in chickens; that is, the virus has changed and adapted to the new species.

Duran-Reynal presented examples and data to support his statements.

safety of vaccine have been strengthened by improving sampling procedures for tissue cultures and by increasing the sensitivity of the monkey tests. These measures, along with improvements in the processing, increase the assurances that vaccine which tests negative is, in fact, safe. With these elements of production under control, vaccine production is expected to proceed without delay, interruption, or frequent reprocessing.

Among questions put to the panel by the audience were the following:

Q. How long does protection last?

A. Dr. Salk said children who received the two-shot-plus-booster inoculation still had antibodies reflecting the booster effect after 30 months. Until the program is older, the duration of effect will not be known.

Q. Does the route of inoculation matter? *A.* Shots under the skin or in the muscles are both effective; the timing, the amount, and the antigenicity of the inoculations determine the effects, Dr. Salk said.

Q. Does vaccination prevent subsequent nonparalytic poliomyelitis?

A. The answer to this question is not definitely known. However, vaccination builds up enough resistance to infection to assure that an invasion will be unlikely to produce paralytic effects. There is also evidence that the vaccine may reduce the duration of infection and the amount of virus excreted.

Q. Will the Mahoney strain be superseded? *A.* No strain has been found that appears to confer superior protection against type 1 poliomyelitis. The interim report of the technical committee stated, "Vaccine properly made with the Mahoney strain provides an entirely safe immunizing agent."

Q. Did the vaccine contribute to the 1955 epidemic in Massachusetts? *A.* Dr. Feemster said absolutely not. The Massachusetts epidemic followed the classic pattern of radiation from a focal point. It did not appear in many areas in which vaccine was used. It was not a multiple-focus epidemic.

Poliomyelitis . . .

Poliomyelitis Vaccine Production Advanced

A distinguished panel on poliomyelitis, in general session with the APHA, discussed the Salk vaccine with the assurance that the process of commercial production had been refined and that vaccine can now be produced without interruption.

Following an introductory statement by Jonas E. Salk, M.D., of the University of Pittsburgh School of Medicine, experience with the vaccine was discussed by other panel members: Robert D. Defries, M.D., University of Toronto; Lloyd Florio, M.D., University of Colorado; Thomas Francis, Jr., M.D., University of Michigan; Leonard A. Scheele, Surgeon General of the Public Health Service; and Hart E. Van Riper, M.D., National Foundation for Infantile Paralysis. Malcolm H. Merrill, M.D., director of public health for California, served as moderator.

The panel was assisted by David Bodian, M.D., Johns Hopkins University; Hugh L. Dwyer, M.D., Kansas City director of health; Roy F. Feemster M.D., director, division of communicable diseases, Massachusetts Department of Public Health; and Lawrence J. Peterson, Idaho director of health.

Dr. Salk's paper was supported by an Interim Report of the PHS Technical Committee on Poliomyelitis Vaccine. The committee includes Drs. Bodian, Francis, and Salk, Dr. Carl L. Larson, chief, PHS Division of Biologics Standards; Dr. Richard

E. Shope, Rockefeller Institute for Medical Research; and Dr. Joseph E. Smadel, Walter Reed Army Medical Center; with Dr. James A. Shannon, director of the PHS National Institutes of Health, as chairman. Both Dr. Salk and the committee reported studies which discovered unsuspected hiding places for live virus during commercial production.

Production Changes

In essence, the vaccine is produced by inoculating tissue culture media with a virus strain, filtering, and then treating it with formaldehyde to render the virus capable only of provoking the production of antibodies. In the final stages of production, three single strain vaccines are combined in a "polyvalent" pool.

During laboratory production and in the trial period, there was no evidence of infectious amounts of virus in the vaccine. Under conditions of large-scale production, however, sediments were observed in virus suspension which had been allowed to stand more than 3 days between filtration and treatment. It was reasoned that the precipitates which formed protected virus from subsequent exposure to formaldehyde, with the result that infective quantities of live virus were detected by tests of batches of vaccine. It is now the practice to filter vaccine within 72 hours of the start of inactivation and during the final stages of the formaldehyde treatment.

At the same time, tests for the

better than they used to be, but they are far short of the precision for which they are usually given credit. A certain amount of success has led to a routine acceptance and a lack of critical evaluation."

Although deaths from tuberculosis have decreased dramatically, the reports of new active cases and the number of current active cases are decreasing slowly, if at all. Tuberculosis will be a major health problem for generations unless new tools for control are developed, he asserted.

The basic difficulty in tuberculosis control is the reservoir of infection. Many of the estimated 40 million people who carry live tubercle bacilli will develop active disease, but their number and identity cannot be predicted each year on the basis of present knowledge, he said.

Discussing the deficiencies in laboratory tests, epidemiological data, drugs now in use, Feldmann went on to make the following points:

As a screening test, the survey chest X-ray is poor; at least one-third of the lung area is hidden from view. Also, the experts' subjective errors in reading may result in missing as much as 20 to 30 percent of the films showing significant lesions. The experiments with high voltage diagnostic X-rays, xeroradiography, or multiple views may lead to better results.

There is surprisingly little reliable data on how to use the tuberculin test or on which to determine its practicality. That no one technique or dosage is now considered superior is obvious from the variety of tuberculin tests in common use. Few attempts to relate test results to active cases found or missed have been made. A tuberculin test method suitable for rapid mass use would be welcomed.

In laboratory diagnosis, the current routine procedures for disinfection, as a preliminary to animal inoculation or culture, kill from 80 to 98 percent of the tubercle bacilli in the specimen. If tubercle bacilli are present in large numbers, the labo-

ratory test will be conclusive, but if few germs are present, they may not be detected.

Treatment

Drugs in use are toxic, are not bactericidal, must be given over long periods, and often fail, Feldmann asserted. The exact mode of action is unknown and the clinical applications of the drugs have been built on a trial and error procedure, he declared.

Only pyrazinamide in combination with other drugs can be demonstrated to have an eradicated action in animals with tuberculosis. This supports the hope that a drug or a combination of drugs deadly to the tubercle bacilli could dramatically shorten the time necessary to eradicate the disease.

Research in nutrition may contribute much toward therapy and prevention of tuberculosis, he said. Although limited evidence indicates proteins and the vitamins A and C are of importance, little research is now going on to determine their specific roles.

Bacteriophages active against tubercle bacilli in humans have been conclusively demonstrated only recently. Advances in chemistry are making possible more exact determinations of the metabolism and the complex enzyme systems the bacillus maintains. The many strain variations have led to attempts at better classification and work on the relationships between drugs, virulence, and other attributes. All of this work, Feldmann declared, has focused interest on the possibility of new approaches to an effective vaccine.

Urges Outpatient Therapy For Selected Cases Only

For tuberculosis patients who either cannot or will not be hospitalized, ambulatory treatment is indicated, advised Joseph B. Stocklen, M.D., on the basis of reported effectiveness of such treatment in a

fairly high percentage of patients. Dr. Stocklen is controller of tuberculosis for Cuyahoga County, Ohio, and assistant clinical professor of medicine and preventive medicine, Western Reserve University.

In view of an estimated 85,000 deficiency in tuberculosis beds, there is a choice of neglecting a large number of patients or treating them as outpatients, he declared. By providing outpatient treatment for this large reservoir of active cases, he emphasized, a substantial reduction should be made in the bacterial population and the incidence of tuberculosis should decline.

He based his estimate of bed deficiency on Public Health Service reports of the percentage of known active cases of tuberculosis that are hospitalized, the number of patients hospitalized, and the number of beds available.

Hospitalization, however, Stocklen said, is still the procedure of choice, despite success in outpatient treatment. He recommended that the patient be advised from the beginning that the hospital is the best place to treat tuberculosis both from his own standpoint and from that of the community. But if hospitalization is not possible, he stated, outpatient treatment should be planned for the patient.

Effective and Feasible

Pointing out that the literature offers little direct evidence either to support or to condemn outpatient treatment, Stocklen cited three studies that "appear to indicate that outpatient treatment is effective and feasible in a fairly high percentage of selected cases."

In one study, reported in 1952 by Jane P. McCollough, 61 of 205 selected patients treated with pneumoperitoneum were considered to have inactive or arrested disease 1 year or more after treatment was begun. Except during an initial 3-day period, all treatment was given on an outpatient basis.

In a second study, reported by Arthur B. Robins and others in 1954, 348 unhospitalized patients with ac-

elitis in 1952 and 1955 have been collected from a total of 33 States. Analysis of these data has shown that paralytic attack rates were sharply reduced among children of ages 7 and 8 in comparison with rates for previous years. Langmuir stated that this sharp reduction, limited to the age group in which the great bulk of vaccine was used, constitutes an independent confirmation of the effectiveness of poliomyelitis vaccine as used this year for the prevention of paralytic poliomyelitis.

Louisiana Study Probes Poliomyelitis Immunity

Observations on poliomyelitis infections, under way in a 5-year study of newborn infants and their family associates in about 150 representative households in southern Louisiana, are substantiating many of the inferences drawn from indirect and retrospective data.

Use of tissue culture techniques has enabled the four epidemiologists from Tulane University, who are conducting this first large-scale prospective study, to obtain first-hand information on when and under what circumstances people acquire immunizing infections against poliomyelitis.

Reporting the 109 episodes of infection observed since April 1953 were John P. Fox, M.D., Ph.D., M.P.H., Henry M. Gelfand, M.D., Dorothy R. LeBlanc, B.S., R.N., and Donald P. Conwell, M.D., M.P.H., all of the university's department of tropical medicine and public health.

To determine an infectious state, serum is examined for neutralizing antibodies and stools for virus. Specimens are collected monthly from the newborn index children and annually from the other family associates. Serum specimens and a basic epidemiological record were also obtained on admission to the study. Appearance of antibody or a virus isolation in the index child signals an immediate return to the household for further specimens and

clinical and epidemiological observations.

Subclinical Infections

Among the more than 200 persons infected during the household episodes, Fox and associates reported, about one-third gave histories of minor febrile illness, but none had clinically diagnosed poliomyelitis, even though the infections were caused by viruses distributed as to antigenic type in about the same way as those concurrently causing paralytic disease in the study areas of urban New Orleans and Baton Rouge and the semirural Evangeline area.

The absence of paralytic disease is not surprising, they said, since it has long been recognized that paralysis occurs with only a small proportion of infections. The Louisiana findings go a bit further, they pointed out, by indicating that at least two-thirds of infections produce no obvious symptoms.

Intrahousehold spread to nonimmune members was the rule in these silent immunizing infections just as in families with cases of overt disease, they found. Ninety-five percent of the nonimmune members were infected along with the index child.

Renewal of Immunity

They found also that 20 percent of the previously immune members were reinfected, but excreted little virus. Persons with relatively low titers, median 1:40, were usually

selected for reinfection. This "fairly unique" finding, they said, supports the theory that immunity may be renewed by occasional reinfection.

The virus types predominating differed in the areas and time periods. Type 3 virus was most prevalent in 1953-54 and type 1 in 1955. These data indicate that there are cycles of predominance of one or another virus type and that the cycles may be conditioned by corresponding deficiencies in immunity to the different types in the very young segments of the population, they concluded.

The findings on the relation of race, economic status, and family size to the early acquisition of infection and the season of occurrence were similar to those described by previous workers, they reported.

Infections, they found, were most common in Negro households, in families with older nonimmune children, and during the summer months.

Age specific frequencies of seroimmunity to the three virus types were determined for all members of the study households in 1953 and again in 1955. Overall, 60 percent were immune to a given virus by age 4 and 90 percent by age 10.

Immunity developed most rapidly in the Negro group. The white lower economic group followed fairly closely, and the white upper economic group lagged well behind. The immune percentages for the three groups in 1953 were 70, 74, and 64, respectively. These relative positions had changed very little by 1955, they said.

Tuberculosis . . .

Says Tuberculosis Research Needs Prompt Attention

Further advances in tuberculosis research are needed if the disease is to be eradicated or even controlled within a reasonable time, commented

Floyd M. Feldmann, M.D., Dr.P.H., medical director, National Tuberculosis Association, in discussing unresolved problems in tuberculosis research.

"To be brutally frank," he said, "the tools now in use are inadequate for the job. They are immeasurably

RHEUMATIC FEVER

There, each tube was incubated for 6 hours at 37.5° C. in Pike's medium. Poured plates were prepared for each culture; at the same time, blood agar plates were streaked from each tube of Pike's medium. Plates were

read out after 24 hours of incubation at 37.5° C. Beta hemolytic streptococci were isolated from the blood agar plates. Lancefield grouping was carried out on these isolated organisms.

Table 1. Group A beta hemolytic streptococcus incidence, by number of cultures

Subjects	Number children	Number cultures			Percent cultures positive
		Total	Positive	Negative	
Rheumatic children, treated	53	1,000	6	994	0.6
Siblings, untreated control	104	705	45	660	6.4
Total	157	1,705	51	1,654	3.0

Table 2. Group A beta hemolytic streptococcus incidence, by number of children cultured

Subjects	Number children	Children with at least 1 positive culture	Children with all cultures negative	Percent of children from whom positive culture was obtained
Rheumatic children, treated	53	5	48	9.4
Siblings, untreated control	104	27	77	25.9
Total	157	32	125	20.3

health; Eleanor Thomas, A.B., principal serologist; and Anthony J. Lucci, B.S., senior serologist, New Jersey State Department of Health, Trenton.

New Jersey has been equipped for virus isolation work for a number of years, and psittacosis, had it been present to any extent in prior years, would have been diagnosed, they asserted.

First Evidences

On September 20, 1954, the owners of a small turkey farm at Dutch Neck, N. J., noted that many of their 2,000 birds appeared to be ill and had developed diarrhea. Until November 22, various treatments were tried at the suggestion of a feed salesman, including sulfathiazole, penicillin, streptomycin, and aureomycin, mixing of the dosages in feed or water, and even intramuscular injections. Three hens and a tom died and were taken to Rutgers University for examination on November 1. Four persons who had helped inject the birds on November 2 became ill with virus pneumonia between November 9 and 28.

On November 22, 1954, the poultry diagnostic laboratory at Rutgers reported a positive diagnosis of psittacosis, and the farm was placed under quarantine by the State health department, they said. Birds were not to be sold without inspection. Blood samples were obtained from workers who had helped slaughter birds. Several additional birds were examined.

On November 29 enough oxytetracycline and tetracycline were obtained to treat all human contacts and to start an experiment to cure the birds. Birds that appeared ill or died prior to November 29 were sent to the University of Pennsylvania, where Dr. Raymond Fagan is cooperating in the experiment to evaluate treatment of the surviving turkeys, they said.

Epidemiological Investigations

The farm owners raised no birds for replacement. Each spring, the stock was purchased from 5 sources,

which were diagnosed as psittacosis were attributed to contact with infected turkeys. Most of the cases were in persons who were employed as eviscerators. One laboratory technician was taken ill and believed to have died from psittacosis infection.

Reporting on the situation were Oscar Sussman, D.V.M., M.P.H., chief, bureau of veterinary public

Studies in Zoonoses . . .

Pneumonitis in Workers Linked to Turkeys

Psittacosis virus, which had been recognized in domestic turkey flocks in Texas, is believed to have been disseminated in 1954 in New Jersey by eggs or poults as latent carriers, or by infected shipping containers, three New Jersey scientists said.

At least 17 human cases of illness

tive tuberculosis were treated with isoniazid and PAS for at least 4 months. After 6 months, 39 percent had improved radiologically; no change was observed in 55 percent, and 6 percent showed progress of the disease. Of 222 patients with positive sputum, 99 converted to negative.

In a study of his own, Stocklen found that of 163 active tuberculosis patients treated as outpatients with streptomycin and PAS, 67 did not need hospitalization. These patients were observed for 9 months or longer.

All these studies, Stocklen remarked, were deficient in that the followup period was short and there was no control group. Nevertheless, he considered the evidence convincingly in favor of outpatient treatment in selected cases.

Against Outpatient Treatment

Stocklen mentioned the following arguments against widescale use of outpatient treatment:

1. If the patient is infectious, he

very probably will be a greater health hazard at home than in the hospital.

2. Patients probably receive better care in a hospital than at home and thus the prognosis is probably better.

3. A policy of outpatient treatment may encourage some patients to leave the hospital against advice.

4. Some patients will develop antimicrobial resistant tubercle bacilli after prolonged antimicrobial therapy without conversion of sputum to negative. There is evidence that these organisms have the ability to infect other persons and that they retain their resistance.

In an outpatient treatment program, he said, sputum should be examined and chest X-rays taken at routine intervals. If at the end of 6 or 8 months of outpatient treatment, sputum has not converted to negative or pulmonary cavities have not closed, hospitalization should be insisted on. If the patient will not agree, enforced isolation should be considered.

None were positive. No antistreptolysin-O titers were above 500 units. In 7 families of these children, however, there was evidence of recent streptococcal exposure. Positive cultures were obtained from the nose and throat of one sibling in each of 4 families, and one sibling in each of 3 families had titers above 500.

Hamilton and his associates reported that in the period from January 1954 through October 1955, there were 2 peak seasons for streptococcal infections. Results of cultures for group A streptococci for the 21-month period are summarized in table 1. The protection against infection provided the treated children is indicated in table 2.

The frequency of positive cultures among the untreated was 10 times as high as among the treated children. This could happen by chance only once in 10,000 trials. The difference in the number of children with positive cultures (9 percent of those treated against 25 percent of those untreated) could have occurred by chance only once in 100 times. These data were analyzed statistically by chi-square.

In the study period there were no recurrences of rheumatic activity in the treated children. One untreated sibling under observation showed clinical signs of acute rheumatic fever, his first attack. His condition was recognized promptly. He was put under treatment; and he has been saved from residual cardiac damage.

Untreated children with rheumatic histories have about an even chance of a recurrence after a renewed streptococcal (Lancefield group A) infection. Prophylactic treatment aims to prevent progressive cardiac damage from such recurrences.

Cultures were taken at the Children's Convalescent Center, Kansas City, Mo., from the nose and throat on swabs. These were placed immediately in Pike's base as a transport medium and brought to the microbiology laboratories at the University of Kansas Medical Center.

Rheumatic Fever . . .

Rheumatic Fever Study Uses Sibling Controls

The effectiveness of injections of benzathine penicillin G in the prevention of rheumatic fever was described by Tom R. Hamilton, M.D., in connection with a 21-month study which included, as a control group, 104 siblings of 53 rheumatic outpatients, representing 50 families. While the outpatients were receiving prophylactic injections, their siblings had none.

Collaborating in the study were Antoni M. Diehl, M.D., assistant professor of pediatrics, and John S. May, assistant in microbiology and medical student at the Univer-

sity of Kansas School of Medicine, Kansas City, Kans. Dr. Hamilton is professor and chairman of medical microbiology at the medical school.

The authors in 1954 recommended siblings as a control in such a study on the grounds that members of one family in close contact live in a like setting and resemble each other genetically, with a similar susceptibility.

In the pilot study, benzathine penicillin G had been injected intramuscularly every 28 days in a dosage of 1.2 million units for each of 22 children. Cultures were taken for beta hemolytic streptococci of Lancefield group A from the treated children 28 days after the last injection.

larval or adult trichinae; or direct transmission when pigs eat infected carcasses. Both possibilities were studied by Zimmermann and associates.

The 9 tests in fecal transmission, using either infected rats or foxes as donor animals and either pigs, rats, or foxes as receptors, all proved negative. This should not rule out the possibility of fecal transmission, they stated, for other workers have carried out positive fecal transmission experiments.

It is difficult to ascertain what role, if any, rats and wildlife may play in the perpetuation of trichiniasis in grain-fed swine. Since trichiniasis is found in many of the species of wildlife, such species are an obstacle to the eventual elimination of this disease. This is true especially if a link is found between trichiniasis in swine and its reservoir in the wildlife. Then, the trichiniasis problem will only be more clearly defined, not eliminated, they said. It would be impossible, as well as impractical, to eradicate all species of wildlife which may act as reservoirs.

Human Brucellosis Yields To Antibiotic Therapy

Streptomycin and sulfadiazine and other antibiotics have proved to be effective in the treatment of brucellosis—undulant fever—one of the more common diseases transmissible from animals to man, according to Wesley W. Spink, M.D., professor of medicine at the University of Minnesota Medical School, Minneapolis.

Spink pointed out that the causative bacteria are excreted in the milk of cows, sheep, and goats. Man contracts the disease by drinking unpasteurized milk obtained from infected animals. Another mode of transmission is by direct contact of humans with infected animals or their contaminated environment. Employees of meatpacking houses, livestock producers, farmers, veter-

inarians, and laboratory personnel are most likely to be exposed to the infection.

The disease causes acute symptoms resembling those of influenza, and a chronic and debilitating illness may result, Spink said. Since therapy is now available, prognosis depends largely upon prompt diagnosis and proper treatment, he said. A brucella agglutination test and blood cultures are the only sure determinants of the infection.

The first major breakthrough in treatment occurred in 1947, Spink reported, when a patient with subacute bacterial endocarditis provoked by *Brucella abortus*, hitherto fatal, responded favorably to a combination of streptomycin and sulfadiazine. The patient since has had no recurrence.

Effective results were obtained with aureomycin in 1948 at the Minnesota Medical School, when 90 percent of the patients treated recovered with treatment of this drug alone. Aureomycin has an advantage over other drugs in that it can be administered orally in capsules. An effective course is 2 capsules (0.5 gm.) four times daily for 21 days, Spink said.

More recently, tetracycline has been tried and found promising, Spink said. There is some evidence, he reported, that a combination of streptomycin and tetracycline may yield better therapeutic results in severe cases than the use of tetracycline or aureomycin alone.

Approximately 300 patients have been treated at the University of Minnesota Medical School from 1937 to 1955, he said. Because of the improvements in antibiotics, he declared that it now can be concluded that in a properly treated group the course of the disease is shortened, new complications do not occur, and complications that are present can be eradicated.

Eradication of the disease, Spink concluded, is dependent upon elimination of the reservoir of the infection in beef and dairy cattle, swine, goats, and sheep.

Teamwork in Texas Ends Rabies Threat

When the number of animal rabies cases reported in Harris County, including Houston, Tex., reached a peak of 486 laboratory diagnosed cases in the latter part of 1953, it aroused citizens as well as officials to take emergency control measures. Their efforts, started in 1954, resulted in a rabies-free month in October 1955.

The events leading to what became the largest mass vaccination campaign against rabies ever conducted in the United States were described by Ernest S. Tierkel, V.M.D., M.P.H., chief, Rabies Control Activities, Communicable Disease Center, Public Health Service, Atlanta, Ga., Fred K. Laurentz, M.D., director, Houston Health Department, L. D. Farragut, M.D., M.P.H., director, Harris County Health Unit, and Reuben D. Wende, M.S., director, Houston Health Department Laboratory.

Although rabies incidence in the area had been carefully observed for 10 years, no organized control effort was made until after the high or record-breaking incidence was reached, they said.

The first control effort, a vaccination and leashing ordinance passed in 1945, applied only to the city of Houston. This was ineffective since animals exposed to rabies were often abandoned outside the city and became stray animals providing a reservoir of infection, they commented.

Campaign Organization

The health department, in 1954, through the newspaper accounts and radio broadcasts, stimulated the public to act, they said. A Citizens' Rabies Advisory Committee was formed to inform the public, to coordinate control activities in city and county, and to gain community support for further control activities. Both health departments, medical and veterinary societies, farm groups, civic clubs, and the mass

3 in New Jersey and 2 in Pennsylvania, they reported. The Pennsylvania sources were referred to the State health department at Harrisburg.

At an Elizabeth slaughterhouse it was found that 2 of the 6 workers were ill. This plant had purchased birds from the stock farm.

One source at Englishtown, used by the Dutch Neck farm to replenish its stock, handled poult. It also acted as agent for a New Brunswick hatchery which purchased eggs from the two Pennsylvania sources and from Texas and southwest California. At Englishtown 4 of the 5 workers were ill with severe colds during July and August, possibly from contact with infected poultry. The 19 bird serums tested indicated that there was probably little active infection at Englishtown. Two serums reacted at 1:8, three at 1:4.

A second source of supply, Turnersville, had no sick birds. The owner regularly included antibiotic in the feed, however. The owner had had bronchitis after Thanksgiving in 1953 and 1954; his serum titer was 1:4 as was that of one of the workers. Another worker had a 1:64 titer and reported a bad cold after Thanksgiving. This source purchased eggs for hatching from Texas and also bred some of its own stock.

The third New Jersey source was at Cranbury. The owner purchased poult and eggs from Connecticut and Oregon sources, neither of which dealt with Texas firms. No illness was found in the birds.

Laboratory Procedures

The indirect complement fixation technique was used to test the birds and the direct test was used in human serums. Lygranum antigen and high-titered human serums were used in place of positive pigeon serums. For humans, lygranum antigen or psittacosis antigen, supplied by the PHS Communicable Disease Center, was used.

Aliquot portions of human and of turkey serums were sent in some in-

stances to the CDC and the Hooper Foundation in California. Correlation of results from both laboratories were within limits of acceptable variations, they reported.

A 9-month serum sampling of the workers affected indicate significant reactions and corroborate prior diagnosis of psittacosis, they said.

Iowans Find *T. spiralis* In Wildlife Species

Regulations in 47 States which prohibit the feeding of raw garbage to swine may be an important factor in the significant reduction in the incidence of *Trichinella spiralis* in pork products, according to W. J. Zimmermann, Ph.D., L. H. Schwarte, D.V.M., Ph.D., and H. E. Blester, V.M.D., of the Veterinary Medical Research Institute, Iowa State College, Ames, Iowa.

Zimmermann and his associates examined various pork products to determine the incidence of trichinae larvae. This study of 1953-54 as compared with the 1944-45 study in Iowa of trichinae larvae in bulk and link sausage showed 2.2 and 2.4 positive percentages as against 11.9 and 11.4 in the earlier study.

There were 187 cases of human trichiniasis reported in the United States through August 1955, of which 10 occurred in Iowa, they said. The incidence of human trichiniasis has fluctuated widely in the last decade; in 1945, 237 cases were reported in the United States with 133 of these cases occurring in Iowa. However, in 1950 there were 327 cases reported in the United States and none in Iowa, according to Zimmermann and his co-workers.

Although in the past the prime source of human infection was improperly cooked pork from swine which had been fed raw garbage, the source of infection for grain-fed swine remains an unsolved problem, they said. In the recent study, diaphragms of 2,184 swine were exam-

ined. The swine were chosen from four areas of Iowa, from college herds, and from a small packing house. Only one proved positive.

Wildlife Reservoir

To determine if wild animals were the reservoir perpetuating the trichinae, 119 rats were obtained. These included 10 from the Veterinary Medical Research Institute, 17 from a farm, and groups of 61, 20, and 11 from three separate villages and city dumps. Fourteen of the 61 rats from one of the dumps proved positive. This was the same area from which 1 of 687 pig diaphragms proved positive. All other rats in the study were negative.

Eighty-five wild mink were examined during the two seasons of the study. Twelve (14.1 percent) were positive. The finding of trichiniasis in the wild mink is of particular importance since the disease had never been reported from this species in the United States. All ranch-raised mink examined (four) were negative.

Thirty (11.9 percent) of the 252 adult foxes examined during the 2 years were positive. The intensity of the infections was less than in some other species. Only 1 fox cub out of 56 proved positive.

Of 40 opossums only 1 was infected with trichinae. This infection was not intense and is possibly the first reported in this species, they said. Of 229 raccoons examined, only 2 were positive, while there were 2 coyotes out of 4 examined that were infected.

A variety of other animals were examined with negative results. The Iowa study group believes that a possible explanation for the absence of infection in carnivorous birds and snakes is that the body temperatures of these animals do not favor survival of the parasites.

Modes of Transmission

Two possible modes of transmission of trichiniasis from wildlife to swine have been suggested. They are fecal transmission, either of

previous campaign, and how many persons live in the unit.

Unowned Dogs

Stray dogs were assumed to be distributed in the same manner as the dwelling units where food would be most likely available, and a drag-net procedure at sampling points is to be arranged, they said. The drag-net, according to the local humane officers, would be best in the early morning hours when it is cool and the dogs are out looking for food. Thus, they explained, the same sampling method could be used on owned and unowned dogs. When this sample is made in the spring of 1956, the figure will be added to the maximum estimate (212,000) of owned dogs to give health officials the data they need as to actual dog population in the inoculation program.

State Laboratory Confirms Leptospirosis in N. C.

On the basis of recent laboratory tests, leptospirosis appears to be widespread in North Carolina. As a result, serologic tests for leptospirosis now are a routine procedure in the North Carolina State Laboratory of Hygiene.

Nell Hirschberg, Ph.D., bacteriologist, and Lynn Maddry, Ph.D., assistant director of the laboratory, and Martin Hines, D.V.M., chief of the section of public health veterinary medicine, North Carolina State Board of Health, stated that the suspected prevalence of leptospirosis makes laboratory diagnostic services essential at the State level. They advised health officers of other States that cases reported as infectious hepatitis may actually be leptospirosis. Furthermore, whenever leptospirosis is diagnosed among domestic animals, health officers should be alert to the possibility of the disease in humans.

North Carolina is not experiencing the classic Weil's disease, they said, but rather a mild form, usually, but not always, accompanied by jaundice.

Domestic animals, especially dogs carrying *Leptospira canicola*, and cattle carrying *Leptospira pomona*, transmit the infections to man.

Weil's disease is rarely reported in the United States. It usually occurs among persons such as trench diggers and subway workers who work in the ground or who come in contact with rats.

Since the North Carolina laboratory announced the diagnostic service, it has received an increasing number of requests for *Leptospira* tests on patients who have had no contact with rats and who appear to be ill with symptoms resembling those of infectious hepatitis or influenza.

Veterinarians in the State are also receiving an increasing number of requests for *Leptospira* tests on animals, they stated, but apparently there is no correlation between the two types of requests.

Infectious Hepatitis

Hirschberg, Maddry, and Hines reported that until recently only 1 or 2 cases of leptospirosis in humans have been reported annually in the State.

Although only 10 cases of leptospirosis and a similarly small group of serum jaundice cases were reported in 1954, the laboratory results suggest that most of the specific but unreported cases of leptospirosis probably had been reported as infectious hepatitis.

They believe that a large number of cases in the past were reported as "infectious jaundice," a classification which included bacterial and viral hepatitis until the title was changed to infectious hepatitis in 1952. All forms of infectious hepatitis except leptospirosis are now grouped under the single classification on the revised report form.

A 1954 survey showed infectious hepatitis spread over the entire State with large numbers of cases from counties with diagnostic medical centers or occasionally from counties in which there was a well-defined epidemic. All told, there were 1,055 cases of infectious hepatitis reported,

and probably many of these cases were in fact leptospirosis, they stated.

The Test

The choice of serologic tests depends to some extent on conditions in the laboratory performing the tests, Hirschberg and her associates stated.

The agglutination test with formalin-killed *Leptospira* became standard in the North Carolina laboratory in January 1954. The agglutination-lysis test is not used routinely because of the danger inherent in the use of the living, motile organism. When paired serums are available, the North Carolina laboratory sends them to the Communicable Disease Center Laboratory of the Public Health Service for complement fixation.

One of the paradoxes of the disease is the ability of the *Leptospira* organism to remain alive for years in natural waters, to grow in tap water fortified with serum, and yet to disintegrate spontaneously without warning in the laboratory or remain alive without apparent multiplication.

No examples of positive tests have ever been found in individuals who have not been infected with the organism before or who are not ill with leptospirosis at the time. In other words, native antibodies to these organisms are not found. Sixty-three veterinarians who were bled for *Leptospira* all tested negative.

Four standard strains of *Leptospira* are considered sufficient to prepare antigens for routine agglutinations: *Lept. canicola* and *Lept. pomona* as well as the agent for Weil's disease, *Leptospira icterohemorrhagiae*, and the cause of Fort Bragg fever, *Leptospira autumnalis*. Eight other strains were tested to see if infection with exotic strains might also be prevalent in North Carolina.

The organisms are grown in a modified Korthoff's medium for 5 days, killed with 0.3 percent formalin, allowed to stand for 24 hours, then

publicity media constituted the nucleus of the organization, they explained.

A review of human rabies cases in Houston and in Harris County in a national journal gave the campaign impetus. Additional pickup trucks and crews were obtained and a modern animal shelter was built in Houston.

The major wedge into the rabies front came, however, when the Texas State Legislature, meeting in special session, authorized metropolitan counties to require vaccination of all dogs, they declared.

The help of the Public Health Service was obtained at the request of the county health officer through the State health department. An intensified emergency rabies control campaign was charted with the Houston Veterinary Medical Society and the Houston and Harris County Health Departments. The plans called for free prophylactic anti-rabies canine immunization with services donated by the local practicing veterinarians and vaccine and clinic supplies provided by the local governments.

Immunizations

Ninety-two locations were chosen as clinic sites. These were selected on a basis of population densities and rabies incidence. Fire department stations offering large, sheltered work areas with available parking space nearby, were used.

A 4-day schedule was set up, with arrangements made for early evening as well as afternoon sessions. The city and county were divided into four sections. An average of 23 clinic sites were set up in each section.

Because of the publicity, efforts of the citizens' committee, the campaign itself was largely a matter of letting the public know the clinic sites, dates, and time. Newspapers, radio, and television cooperated. Literature and posters were distributed through the city and county school systems, with clinic schedules attached. Although dog regis-

tration or licensing was mandatory in the city and county, the requirement was not mentioned in the vaccination campaign.

Operation of the clinics was kept as simple as possible. With vaccination, a tag and certificate were issued. City and county sanitarians supervised each clinic; one or more veterinarians administered the vaccine; public health and Red Cross volunteer nurses helped prepare the syringes; and clerical duties were performed by Boy Scouts, 4-H Clubs, and other volunteers.

Each clinic began operating with supplies for 300 dogs, but after 1½ hours on the first day practically all clinics had exhausted the supply. Police and sheriff's radio cars were used to deliver supplies. For the following days, supplies were doubled, but still, in some instances, additional supplies were needed, they said.

With the 4-day campaign and a clinic at the dog shelter on a fifth day, 44,390 dogs had been vaccinated, the largest number ever immunized in the United States in one campaign, according to Tierkel and his associates, and with the 20,000 privately vaccinated dogs they gave the county a large population of rabies immune animals.

Decline in rabies incidence was slow from September 1954 through May 1955, they said, but became more rapid through June–September, and no cases were found in October 1955.

Estimates Dog Population By Sampling Procedure

A statistical method for accurately estimating a community's dog population was developed early in 1955 in Harris County, Tex., as part of a rabies control program that originally had been based on a rule of thumb estimate of 1 dog per 10 humans.

Reporting the new method were: Joseph L. Zarefsky, M.S.W., director, research bureau, Houston Community Council; Dale Houghland,

M.P.H., health education director, and Reuben D. Wende, M.S., laboratory director, Houston Health Department. The rule of thumb estimate of the dog population was 100,000, they said. The sampling method gave an estimate of 191,000 owned dogs.

The new procedure stemmed from a request by the Houston Health Department and the Harris County Health Unit after the laboratory reported there had been no sharp decline in the number of rabid dogs found 6 months after a community-wide rabies inoculation campaign, they said. The possibility that the inoculations had not reached as high a percentage of the dog population as thought prompted the request.

Owned Dogs

The procedure had to be developed quickly, without extra funds, they said. Harris County has 1,700 square miles and a population of 1,023,000. Houston has one-tenth of the land and 70 percent of the population.

Essentially, the method is to use a simple probability sample to ascertain the average number of dogs per dwelling unit with a maximum error of 10 percent at the 95 percent probability level, they explained. To find the size of sample required, it was assumed that there was 0.24 dog per dwelling unit as had been found in the 1952 Denver study.

It was found that a sample of about 1,700 dwelling units throughout Houston and Harris County would yield an estimate of the required precision, they reported. On the basis of census tracts in the county, sampling points were allocated in the same proportion as the dwelling units—a tract having 2 percent of the county's dwelling units received proportionate attention, they explained.

The enumeration was completed in about 3 days. The schedule had four questions. The first was on dog ownership and if the answer was "yes," how many dogs were owned, was each dog vaccinated during the

hasten dessication or by turning top soil to put the eggs out of reach of children.

Keep dogs and cats free of worms that endanger the health of children.

Families with small children perhaps should forego having cats and dogs and pets even though this measure is not fully protective in an urban neighborhood.

the University of Michigan School of Public Health.

Like an exotic plague, he said, the communicability of housing decay affects a susceptible population, which, although it eats well, dresses well, and plays well, includes too many who do not live well. The contagion of housing endodecay, which encourages room overcrowding and insanitary practices, and the contagion of housing exodecay, which creates shabby properties with decreasing values, have spread from block to block, from area to area, in all of our major cities.

To combat the plague of housing decay in urban America, a voluntary nationwide civic planning agency was organized to replace public apathy and neglect with ACTION. A.C.T.I.O.N. is the American Council To Improve Our Neighborhoods, and its 60-man governing board represents public health, industry, government, education, finance, civic and trade organizations, labor, and public service.

Vaughan, as one of ACTION's directors, described the work of the nonprofit, nonpolitical organization, which is financed by gifts from many sources.

The Ford Foundation has granted \$250,000 to study impediments—and the means to remove them—to the provision of adequate housing. The Advertising Council has provided public service time and advertising space for ACTION's national education program, which is designed to alert citizens to housing opportunities and problems.

ACTION has opened the first of many local information centers in Cleveland to provide information on housing research techniques, code enforcement, legislation, community organization, and planning.

Enterococcus Indicators Aid in Water Tests

An enterococcus test would be a useful addition to the coliform test in gauging the bacterial contamination

will not eliminate these areas, the filling in of blank land by people, instead of municipal rubbish, will surely outmode them. The fly, the rodent, the mosquito . . . must be eliminated by environmental sanitation practices. Slums must be wiped out, as breeders of unhealthy minds, bodies, and spirits. Food and milk sanitation must achieve superior standards of cleanliness and purity, perhaps through the use of such devices as atomic radiation. Smoke, smog, smaze, and smist must be cleared from the atmosphere by new methods of atomic heat and power and control of stack gases. Cities must be freed from litter."

In the light of the dreams and fantasies that have come true in the past, these goals are not impossible, Cohn declared. "If we blend our dreams with the vital ingredient of courage, we will assure a better nation and a better life in 1975," he said.

National Group To Attack Neighborhood Decay

Nearly half of America's 45 million nonfarm dwellings need routine maintenance to remain in acceptable physical condition. Another 20 million require repairs and improvements or substantial rebuilding to prevent eventual slums. An estimated 5 million slum dwellings must be eliminated and replaced by new homes. This is the target for a public health program envisaged by Henry F. Vaughan, Dr.P.H., dean of

Environmental Health . . .

Urges Work Begin Now On Cities of Future

To match the technological marvels forecast for the city of the future with improvements that will assure a healthful, comfortable environment is the challenge facing the public health engineering profession, said Morris M. Cohn, Sc.D., editor of *Wastes Engineering*, New York.

With a 60 million increase in population expected by 1975, both central cities and fringe areas will experience growth, Cohn predicted. The challenge, then, is to rehabilitate central cities to meet the standards of 1975 and to build fringe communities in a pattern that will be modern two decades hence. It is necessary to plan entire areas on a metropolitan basis, so that the pieces of community life can be integrated into a well-organized tapestry, he said.

"We need a multibillion dollar sewage treatment construction program," he contended, "to provide new facilities and regear old works. . . . We must put billions into industrial waste pollution control programs. Waterworks systems must be expanded and improved to provide water of unimpeachable palatability, serviceability, and safety to meet the needs of 225 million people. Drought control and flood control must be achieved, not only by engineering structures, but by learning how to anticipate the vagaries of nature. . . .

"The refuse dump must be outlawed as an incongruity in modern community life. If our standards

centrifuged and used after 48 hours. The antigens remain satisfactory for 10 to 30 days. The test is not a suitable one for small laboratories, they said.

Results

Apparently there was no correlation between the infectious hepatitis reported and the specimens tested with regard to location, age, sex, or color. Of 441 specimens tested, 109 were positive. Twenty-nine agglutinated *Lept. canicola* and 36 *Lept. pomona*. The remainder showed cross agglutination.

Most of the specimens came from school children and also from adults in the age group between 30 and 34 years. Hide workers accounted for 21 of the positives, but 61 were unaccounted for. The rest were from housewives, caretakers, nurses, physicians, farmers, food-handlers, morticians, and factory workers.

The North Carolina laboratory does not routinely test animal specimens, but serums were received from animals associated with human leptospirosis. However, the new animal diagnostic laboratory in the State occasionally referred icteric serums from animals in which the diagnosis was obscure.

Of the 93 animals tested, 69 tested positive with some degree of cross agglutination but less than was experienced with the human specimens. Fifteen of 18 dogs were positive, 10 with *Lept. canicola*. Thirty-seven of 49 cattle were positive, 31 with *Lept. pomona*. Positive specimens were also distributed in low numbers among swine, horses, goats, mules, and sheep.

Visceral Larva Migrants— A Public Health Problem?

Recent studies show the dog to be an important reservoir of visceral larva migrants, a newly recognized disease responsible for long periods of subnormal health in young children, according to Paul C. Beaver,

Ph.D., professor of parasitology, Tulane University School of Medicine.

Visceral larva migrants was so named because the causative agent, a nematode larva, *Toxocara*, migrates extensively in the internal organs much the same as the hookworm larva that produces cutaneous larva migrants migrates in the skin, Beaver said. One feature of the infection is that the larva of *Toxocara*, a common worm parasite of dogs and cats, can invade nearly all tissues of children. The larva undergoes several weeks of active migration and can persist alive for months. Dogs and cats are natural hosts for *Toxocara*; man is not.

Beaver reported that a high percentage of dogs the world over have been host to *Toxocara canis*, that *Toxocara* eggs are eliminated in the feces, and that surface soil samples from urban dooryards show hundreds of viable eggs in a few grams of soil. The eggs will remain infective in damp soil for months if permitted to accumulate. Many *Toxocara* eggs destined by nature to find their way into dogs and cats are swallowed by toddlers known as dirt-eaters, he said.

"In well-organized communities popular sentiment in favor of further limitation of the freedom of dogs, even those walked on a leash, probably is ready for public expression," he said. "It is not now a question of whether promiscuous defecation by dogs is a public health hazard. The real question is whether a way can be found to discuss this public health problem openly and to reach agreement on acceptable control measures."

Newly Described

Beaver said that the incidence of visceral larva migrants is unknown. In the absence of satisfactory methods of serologic diagnosis, proof of infection is based on biopsy or autopsy findings. Further, the disease, though doubtless ancient, was first recognized in 1952 in New Orleans. Reports show that the dis-

ease is gaining recognition outside Louisiana, and *Toxocara* larvae may have caused at least one human death, he added.

Symptoms of *Toxocara* infection vary with the number of larvae involved and the duration of the infection. Light infections usually are well tolerated, and the majority of infections probably are subclinical. Clinically, the disease may resemble pneumonia, miliary tuberculosis, asthma, whooping cough, eosinophilia leukemia, and retinoblastoma.

A sharp increase in the number of circulating eosinophils is conspicuous in all *Toxocara* infections. Even in the absence of apparent symptoms, the number of eosinophils may exceed 50 percent of the total leukocytes. Formerly, the disease was often referred to as Loeffler's syndrome, familial eosinophilia, tropical eosinophilia, leukomoides disease, and eosinophilic pseudoleukemia.

The child with moderate infection usually has fever, an enlarged liver, and some degree of pulmonary infiltration in addition to the marked increase in eosinophils, he continued. With heavier infections, these symptoms become more marked, and a history of dirt-eating is usual. There may be cough, muscle and joint pains, and abdominal pains. Occasionally there are impetiginous lesions on the buttocks and legs. Less often there are convulsions and petit mal attacks and infections involving the eye.

Individual Control

Since no specific treatment for visceral larva migrants and no effective method for killing *Toxocara* eggs in the soil are known at present, prevention becomes of chief importance, Beaver emphasized. He listed the following means of prevention to help parents protect their young children from possible infection in the absence of rigid dog control:

Prevent children from eating dirt.
Destroy *Toxocara* (to some extent) by working surface soil to

culties formerly encountered in weighing and analysis, he said.

The sampler mounts an 8"x 10" rectangular filter sheet in a stainless steel holder giving an effective filter area 7" x 9", or 63 sq. in. Air is drawn through the sampler by a vacuum cleaner type motor, initially at 50-60 c.f.m., with a drop in flow rate as sampling proceeds. The filter is reported to be 99.9 percent efficient for particles as small as 0.1 micron in diameter, he remarked.

Describing other air sampling methods, Tabor mentioned dustfall sampling through sedimentation as the oldest and most widely used method. Particulate matter falls by gravity or is carried by rain into a jar with a mouth of known size. A trapping liquid, usually water, prevents the dust from blowing out again. The weight of solid material collected during a month is reported as tons per square mile. The material collected is easily analyzed. The British have adopted a standard dustfall apparatus, and attempts to standardize are now going on in the United States.

Other samplers using the sedimentation principle are a directional dustfall collector and a settlement dust counter, he said.

Impaction sampling uses deflection of an air stream to collect particles for counting and sizing. By their momentum during a sudden change in airflow direction, the particles are deposited on a prepared surface. Available devices using this principle are the Owens jet dust sampler and the cascade impactor, he reported.

Thermal precipitation depends on the phenomenon of the dust-free space adjacent to a hot body. If dust-bearing air is drawn through a narrow channel past the hot body, the particles are deposited on nearby cold surfaces. Devices using this principle have a sampling head with heating and cooling devices and an air pump. There are several thermal precipitators available, and the devices are very efficient for collecting particles smaller than 5 microns, he declared.

Electrostatic precipitation samplers operate on the principle of the attraction of charged particles to an electrode of opposite charge. These devices are nearly 100 percent efficient for collecting particles below 5-10 microns. There are a variety of these samplers available. Collection of samples free of any medium is a major advantage of these devices, Tabor said.

Reviews Cook County's Disposal Difficulties

A "blow by blow" account of the mismanagement of sewage disposal installations in the expanding municipalities and subdivisions of suburban Cook County, Ill., was presented by Benn J. Leland, M.S., chief sanitary engineer of the county's department of public health.

Cook County, the largest county in Illinois, includes, besides Chicago, an area of 750 square miles and a population of about 800,000. Chicago's suburbanites dwell in 100 incorporated municipalities and in a great number of subdivisions. Such subdivisions have their own water supplies, wells in the front yards and seepage fields in the backyards. The seepage of septic tanks has produced a harvest of nuisances and health hazards in much of suburban Cook County.

However, the problems are not confined to subdivisions. A number of municipalities are not served by domestic sewer systems. Most of these communities have exercised less control over sewage disposal than the unincorporated areas.

Impervious clay soils are prevalent in the county. Most complications have arisen because individual seepage fields could not absorb septic tank effluents, which were therefore discharged in surface pools, roadside ditches, or creeks, creating odor nuisances and health hazards. Reports from 25 sanitary engineers serving other county health departments revealed that similar situations exist elsewhere in the United States, Leland said.

Construction

Residential construction increased sharply in the years after 1950, and building sites in areas served by sewers and public water supplies became ever more scarce. Most developers felt they could not finance installations of public facilities to new areas. They have perforce built residences with individual septic tank systems for sewage disposal.

In addition, since Cook County zoning ordinances permit lots of 10,000 sq. ft. in certain areas, many developers endeavor to have their lots reclassified from farming, 5-acre, 1-acre, or 1/2-acre zoning to the 10,000-sq.-ft. category, which provides the maximum number of building sites on a tract.

"While a lot of 10,000 sq. ft. is a good sized lot if public water supply and sewerage facilities are available, in many instances it is not possible to install adequate private facilities on such a limited lot area," said Leland.

All this has resulted in an avalanche of complaints to the public health department, which makes inspections and advises home owners of necessary improvements. If voluntary compliance is not secured, the department initiates enforcement action, but, ironically, such action must often be taken against property owners who perhaps have not even been aware of having been served by a septic tank and seepage system until it has failed.

Percolation Tests

In 1954, an ordinance was passed requiring that plats of proposed subdivisions, to be accepted and approved, must contain certifications that water supply and sewage disposal facilities conform to standards of design and safety adopted by the county's department of public health.

A report on soil percolation tests by a "qualified registered professional engineer" was required to accompany plats if individual sewage disposal systems were to be used. However, the ordinance did not call for the review of such reports by the public health department, although an interdepartmental arrangement

tion of well water, particularly when the coliform values are low or fluctuating.

This conclusion was drawn from a comparison of the two tests on water samples from 595 wells in 12 Kansas counties. To check the results of single samples from each well, an additional 86 samples from 59 wells were examined at intervals of 2 weeks to a year after the first sample. Detailed information on the physical aspects of each well was supplied through a questionnaire.

The study was conducted by Cassandra Ritter, M.A., chief bacteriologist, Ivan F. Shull, B.S.C.E., M.P.H., chief of the general sanitation section, and Robert L. Quinley, A.B., assistant bacteriologist, division of sanitation of the Kansas State Board of Health, University of Kansas.

The coliform MPN index was determined according to standard methods. For the enterococcus MPN determinations, the azide dextrose broth of Rothe, favorable to the growth of all enterococcus groups, was the presumptive medium and crystal violet azide broth the confirmatory medium. Another method in use, they explained, is selective for *Streptococcus fecalis*.

The coliforms and enterococci found in the well water samples were comparable in number, they reported (see diagram). Statistical evaluation showed the association of these two groups of bacteria was not by chance.

Results from 269 samples were negative in both tests, they found. At the other extreme coliforms in excess of 1,100 were always accompanied by enterococci. The 83 samples with enterococci alone and 49 samples with coliforms alone, plus the changes in numbers and relationships found in the check samples, suggest that the enterococcus test may be most useful when coliform values are low or indeterminate, they said.

Favor Inclusive Medium

Of the 424 enterococcus strains isolated from 80 samples selected at random, 284 were typical of *Streptococcus fecalis* and 140 fell into the atypical group. Of the 28 samples with atypical strains only, 78.6 percent yielded no coliforms. A high percentage, 84.6, of the 52 samples with typical enterococci was associated with coliforms in appreciable numbers.

It is possible, they said, that samples showing only atypical enterococcus recoveries may have contained typical strains at the source. However, their observations suggested that typical enterococci will be recovered if present since their growth is faster than that of the atypical strains.

Ritter and associates concluded that an inclusive medium is the method of choice for determining enterococci in water and compares with the standard method for determination of the coliform group.

Their evaluation of the physical aspects of the wells according to the coliform MPN index indicated that construction of the supply is more important than location. A greater degree of sanitary safety was suggested for the 453 drilled and driven wells. A coliform index of less than 2.1 for 70 percent of this group was reported; 13 percent had an index value greater than 28. Of the 121 dug wells, 18 percent had an index lower than 2.1 and 58 percent an index higher than 28.

Reviews Various Devices For Sampling Air

A review of several available sampling devices for the collection of suspended particulate pollutants from the atmosphere was presented by Elbert C. Tabor, M.S., of the PHS Community Air Pollution Program. He discussed in detail the filtration air sampling method used by the National Air Sampling Network and the Robert A. Taft Sanitary Engineering Center.

The network sampler is a modification of a high volume filtration sampler constructed by Silverman and associates in 1948. The modified version uses a glass fiber filter web instead of the pleated cellulose filter originally used. The glass fiber material is not affected by moisture and contains no organic substances. These features avoid diffi-

Scatter diagram relating to the most probable number indexes of coliform bacteria and of enterococci of 607 samples from 595 wells

was made whereby the department does review these reports for the county map officer.

Leland is of the opinion that it is not realistic to ask developers to submit results of percolation tests when these results determine whether a plat is accepted or a building permit issued. He felt that health department sanitary engineers and sanitarians should run all percolation tests. But many agencies other than the county department of public health are concerned with sewage problems in Cook County.

Recommendations

In 1946, the Public Health Service recommended that water supply and sewage disposal activities in the unincorporated areas of the county be transferred to the county department of public health. No action has been taken on this proposal to date, according to Leland.

A recommendation to the Cook County Board of Commissioners that only lots of 20,000 sq. ft. minimum

size be allowed septic tank systems was opposed by builders who argued for consideration of each area on its own merits. This recommendation was not adopted, but the board of commissioners decided to call a hearing at which experts were to present facts on the problem.

As a result of this hearing, a special committee was appointed in 1955 to review the entire situation and to submit legislative recommendations. In addition, several county commissioners made personal investigations and decided emergency action was needed.

All these and other recent activities have successfully induced developers to consider the installation of public sanitary sewers systems with connections to an interceptor sewer or to a community sewage treatment works. Consulting engineers are developing cost data for such facilities which they claim can be installed in average sized subdivisions for a gross cost not greater than the combined cost of individual systems.

program, Sachs maintained. She urged the experienced public health practitioner not to be deterred by the complexity of nuclear physics from applying his skills to the management of ionizing radiations.

The basic epidemiological concepts of agent, host, and environment can be adapted to the problems of radiological health, she stated. Providing expert guidance are the recommendations of the National Committee on Radiation Protection, which are available in National Bureau of Standards handbooks. These cover technical procedures for measuring radiation, methods for protection against it, and permissible exposures.

As a nucleus for a radiological health team, Sachs suggested the following: a physician from the tuberculosis or cancer control program or the occupational health group, an industrial hygiene engineer, and a sanitary engineer. Short training courses will greatly assist in bringing the radiation team to top efficiency, she stated.

The Environment

Control of the environment, Sachs said, is the most fruitful field of endeavor in protecting against harmful effects of radiation.

Shielding, restriction of exposure time, distance, containment, adequate ventilation, proper disposal of radioactive wastes, and protective clothing and equipment are effective barriers to agent-host interaction, she noted.

The availability of these measures, however, does not guarantee that they are always employed in the manner and to the extent necessary to provide full protection, Sachs stated. It is her opinion that some community agency must provide radiation users with the advice and encouragement needed to conserve the public health.

So far, it does not seem possible to alter the host, as by an immunizing process, although in some instances the host can be selected. Sachs remarked that a careful medical history, blood counts, and physi-

Radiological Health . . .

State-Local Help Needed In Radiation Protection

State and local health departments have a wide area of responsibility in radiological health, asserted Miriam Sachs, M.D., chief of the bureau of adult and occupational health, New Jersey State Department of Health, Trenton.

The Atomic Energy Commission's radiation protection system includes strict regulations governing reactor-produced radioisotopes, but the commission does not control X-ray machines, fluoroscopes, naturally occurring radioactive materials, or most nonreactor-produced radioisotopes, she explained.

In recent years, the use of X-radia-

tion and natural sources of gamma radiation, as well as the availability of atomic-pile-produced radioisotopes, has increased, she declared. In many industrial plants, research laboratories, and hospitals the total exposure to radiation includes radiations from X-ray machines, radium, and manmade radioisotopes.

Sachs pointed out that although radiation sources are potential hazards they need not be serious in practical use. Radiation protection, she emphasized, should be thought of not as prohibition of use but as encouragement of use with proper precautions based on respect for possible injurious effects.

Every well-organized health department has the facilities and personnel to begin a radiological health

Milk, Fish, Fruit Juice Tests . . .

Not All Juice Coliforms Stem From Processing

Coliform bacteria in frozen concentrated orange juice are not necessarily an indication of direct contamination, stated E. R. Wolford, B.S., bacteriologist, Western Utilization Research Branch, United States Department of Agriculture, Puyallup, Wash.

Despite the best possible sanitary practice during production, these organisms will occur occasionally, he said. Nevertheless, millions of gallons of frozen orange juice have been consumed since 1916 without any enteric infection reported.

The presence of *Escherichia coli* in concentrated orange juice should not be condoned, Wolford emphasized, but "to condemn the product on the basis of water standards or carbonated beverage standards could

deprive the public of a wholesome, essential food."

Coliform Sources

Reporting on his investigations into the sources and possible significance of coliforms in citrus fruit products, Wolford said that apparently some coliforms are present among the normal flora in orange groves. The fruit examined in the study was picked aseptically into sterile bags or was transferred to sterile bags from field boxes and conveyors by the use of sterilized tongs. The bags were closed and stapled and remained so until they were opened in the laboratory. Nevertheless, *Aerobacter* was found on seven samples of oranges, some of which were grown in groves where no organic fertilizer had been used for 3 years. *E. coli* was found in a sample of fruit from a grove which had been fertilized with barnyard

fertilizer shortly before the fruit was picked.

Packinghouse wash-tank solutions may be one of the principal sources of coliforms in frozen orange juice products, Wolford continued. These solutions may contain many coliforms, including *E. coli*, he said, and, although all oranges used for juice are rewashed at the concentrate plant, fruit with breaks in the peel, particularly weak fruit picked late in the season, may have absorbed some of the contaminated solution at the packinghouse (see photograph). Most packinghouses use these solutions more than once. In some, they are changed once a week; in others, once a season.

Procedures for cleaning fruit also differ among packinghouses. Some houses use a single tank containing both soap and borates, borates only, or soap only; others use two tanks, one containing soap solution and the other containing borates, caustics, or hypochlorite solution.

In the concentrate plants, Wolford said, coliforms were most frequently found on equipment on which decaying orange tissue had been allowed to accumulate. Coliform-positive juice and concentrate were apparently associated with the condition of the fruit itself rather than with insanitary conditions in processing, he concluded.

Penetration of dye solution into orange, indicating how wash-tank solutions can enter through breaks in rind.

Enterococci Best Indicators In Frozen Fish Tests

Use of fecal streptococci to indicate the bacterial content of frozen fish and fish products was advocated by three faculty members of the department of bacteriology and public health, University of Massachusetts.

The testing procedures for the isolation of fecal streptococci are simpler than those using coliform bacteria as indicators, and the results are more significant, they found.

Conducting the study were Edward P. Larkin, Ph.D., instructor, Warren Litsky, Ph.D., associate research

They mentioned these: (a) the effects of interactions between soil and waste material, (b) the movement of critical nuclides through various soil formations, (c) the effects of high concentrations of stable salts on the ability of the soil to retain nuclides, and (d) the underground flow pattern of waste solutions as compared with groundwater flow.

The management of radioactive wastes may well prove to be one of the limiting factors in achieving optimum benefits from the general usage of nuclear energy, Morton and Struxness emphasized in conclusion. Helping to find rational solutions to the problems of radioactive wastes, they said, is a challenge to the sanitary engineer. He must gain an acquaintance with principles of nuclear phenomena and with the techniques of radiation monitoring and control. With regard to ground storage of radioactive wastes, he should arrive at decisions based on an understanding of the hazards and a thorough knowledge of the scientific bases for particular proposals.

Links Radiation of Thymus To Thyroid Cancer

Indications that thyroid cancer in childhood may be associated with exposure to radiation in infancy were tentatively suggested in a study reported by C. Lenore Simpson, M.D., M.A., associate cancer research pathologist, Roswell Park Memorial Institute, Buffalo, N. Y.

This study was instigated to determine the effects of radiation in later life. Infants who received radiation to the thymus gland would be a good group for preliminary study since these children have a long life expectancy and records of X-ray treatment are readily available, Simpson said.

Accordingly, the medical histories of 1,722 children who had received radiation to the thymus between 2 and 27 years previous to the study provided the basis for this research.

She stressed that the findings thus far are all tentative.

The names of the children were obtained from the records of both hospital and private practices. Data were collected by a questionnaire sent to the parents and were supplemented by information obtained from doctors, hospitals, and State cancer records, Simpson said. Most of the children are from New York State.

Occasionally, children were interviewed personally. All available pathological reports and slides were seen. Of the original group, 1,502 were traced and information was obtained concerning 1,933 of their untreated siblings, Simpson reported.

Simpson said that the children had been treated for a variety of reasons. In some cases, thymic enlargement was suspected, and in others routine fluoroscopy of X-ray was carried out to exclude thymic enlargement either after birth or by a pediatrician attending the child later.

In many instances, Simpson related, it was not known which reason was involved in the treatment of each particular child. Generally, she said, it was assumed that the majority of these children were thought by some physician to have an enlarged thymus.

Incidence

This study indicates, Simpson said, that the incidence of neoplasia is high among children receiving radiation to the thymus. Untreated children with enlarged thymus glands diagnosed by the same criteria would have been the preferable control group. Since this was not possible, the treated children were compared with their own untreated siblings and with the general population.

She also compared different subgroups in the study. The 220 untraced children were included in the calculations as being alive and well. The calculations, Simpson stated, have been based on the years at risk of each child and on the age- and sex-specific incidence rates of the disease. For the general population,

the 1949-51 cancer incidence rates for New York State were used, Simpson said.

In comparison with untreated children and their untreated siblings, the treated patients have a relatively high incidence of leukemia and of thyroid disease. The siblings, in the absence of known thymic enlargement and radiation, were considered, Simpson said, a good control group from the point of view of heredity and environment.

Groupings

The study group was divided into six subgroups that represent the different sources of material. The differences in the incidence of tumors among the subgroups was studied and it was concluded that the large number of cases in one of these subgroups was not related to "chance," Simpson said.

The type of treatment in this subgroup differed considerably from that of the other subgroups and it was hoped that this might help to determine whether or not the increase in incidence was due to radiation. At the time of this comparison there were so many variables, Simpson said, that only a tentative conclusion was reached.

Analysis of the treatments was difficult throughout the study, Simpson related. The dose received by the majority of the children was estimated in roentgens. The children in the previously mentioned subgroup received more roentgens than those of the other subgroups; they were also treated with larger ports than those in any other subgroup, and the treatments were at intervals of 2 weeks instead of at 1 to 2 days as they were in the other subgroups.

The relatively small number of neoplasia cases throughout the entire study precluded a definite conclusion. However, it was significant that no thyroid nodules occurred in children who received less than 200 roentgens, Simpson said, whereas, leukemia cases were broadly distributed among the dose range and subgroups.

materials as penicillin, aureomycin, terramycin, streptomycin, polymyxin B, neomycin, bacitracin, and sulfa combinations, they said. However, this test is not specific for individual antibiotics.

Experiments show that this disc assay method is sensitive to quaternary ammonium compounds only above 50 p.p.m., a level extremely unlikely in field practice, Morris and

his co-worker said. Also numerous tests to show precision of negative results on antibiotic free milk were 100-percent effective.

Undoubtedly, Morris and Cerny said, the occurrence of inhibitory characteristics is more frequent in pasteurized milk from areas where antibiotics are used for mastitis reduction without rigid laboratory and field programs.

A fairly long list with few of any particular kind of colored algae, colorless protozoa, worms, rotifers, and other organisms suggests a low biochemical oxygen demand, a low nutritive threshold, and an inorganic substrate. In such a condition, there are enough bacteria to support low numbers of ciliates and flagellates and enough nitrates and phosphates to support a small but varied chlorophyll-bearing population.

Blooms

A large population of diatoms and green plankton algae with a scattering of Euglenophyceae and colored dinoflagellates often means a substantial phosphate and nitrate content, he said. Should these concentrations exceed 0.015 and 0.2 p.p.m., respectively, the green organisms may "bloom," that is, exceed 500 per milliliter. Such blooms may clog filters and affect taste and odor.

If additional organisms such as blue-green algae are added to the bloom, the biochemical oxygen demand increases and filter and odor or taste problems may become acute, said Lackey. Other undesirable effects are implied by extreme blooms, such as restrictions on the development of species other than the species chiefly responsible for the bloom. Lackey said it was highly probable that the poisoning of fish, shellfish, and crustaceans by the marine "red tide" of the Florida coast is a result of an extreme bloom.

Other Indicators

If the sample contains a scant number of organisms and a preponderance of no specific type, the water contains a low mineral content and virtually no organic matter. If the water is barren, Lackey said, it might indicate the presence of toxic substances.

Predominance of anaerobic flagellates such as *Tetramitus* is a sure indication of a high organic content and no dissolved oxygen. The same, with inorganic salts, is implied by predominance of anaerobic green forms such as *Chlorogonium* and

Water Quality Tests . . .

Microscope Reveals

Water Quality

Quick appraisal of certain water characteristics through microscopic determination of the quality and quantity of biota in samples was proposed by James B. Lackey, Ph.D., professor of sanitary science, University of Florida, Gainesville, Fla.

New emphasis has been placed on the simplicity of this method, according to Lackey, by the 10th edition of *Standard Methods for the Examination of Water, Sewage and Industrial Wastes*. Though only strong indications rather than positive and detailed information of the quality of the water as a health hazard are given by such a procedure, pertinent data on the general condition and corrective treatment requirements of the water are revealed.

Although the microscope method is unsatisfactory for the determination of pathogenic bacteria or parasites, it does not necessitate waiting for cultures to develop and is especially suitable for investigating the utility of nonpotable waters.

In addition, preparation and concentration of samples is relatively simple. About 500 ml. is collected and transported from the source in chilled, nontoxic containers. Most indicator organisms in such samples

can be identified in the living state or after killing with a preservative such as formalin.

Lackey preferred centrifuging 5 minutes at 2,000-2,400 r.p.m. to filtering for concentration. The amount of supernatant discarded should vary inversely with the abundance of organisms in the sample. He went on to describe the "drop method" of counting as set forth in the standard methods manual.

Telltale Biota

Indicator organisms are simply listed as ciliates, green flagellates, and so on as they are met, then tabulated. "Generally speaking," Lackey said, "those organisms most favored by a given environment will be most numerous, while those adapted to the widest environmental range will occur in the greatest number of samples." The organisms found in greatest number probably represent a response to some particular characteristic of the environment.

If plankton content is high or consists largely of diatoms, it is a signal that filtration will be difficult, Lackey said. Measures for reducing unpleasant odors or tastes and boiler water slime depend upon the kinds and numbers of organisms present. Some specific trade wastes may be recognized by the microscope method.

professor, and James E. Fuller, Ph.D., research professor, in the department.

Lack of a dependable test organism and lack of standardized methods of isolation have handicapped the food industry and health agencies in the scrutiny of frozen food products, they indicated.

Comparison of the coliform bacteria and fecal streptococcus techniques was made on 80 samples of commercially packed fish and fish products, purchased from stores in several western Massachusetts cities. Seventy-five of the samples had been precooked; the rest were raw.

For the 20 fish stick samples examined, the MPN index of coliform bacteria in lactose broth ranged from 0 to 230. Most of the samples showed MPN values of less than 20. In the confirmatory brilliant green lactose bile (BGB), the values ranged from 0 to 130, most of the samples showing a zero value. The MPN values of fecal streptococci in ethyl violet azide broth ranged from 20 to 16,000 for the same samples, with most of the values more than 500.

Eighteen samples of scallops showed a similar picture. The MPN values for coliform bacteria in lactose broth ranged from 0 to 330; in BGB, from 0 to 130; and on eosin methylene blue, from 0 to 2,400.

Similar results were obtained with codfish cakes, ocean perch, crab cakes, seafood dinner, fried clams, haddock, shrimp, and lobster. Fecal streptococci were present in most of the samples, the MPN values ranging from 0 to 24,000.

Total plate counts, made on tryptone glucose extract agar, were of little value in the examination of frozen fish products, they found. Only in cases of gross bacterial contamination were the plate counts sufficiently high to cause concern. Most of the fish products tested had bacteria counts of less than 3,000 per gram, they reported.

Hand Blending Adequate

In blending the samples, the effectiveness of shaking the material by hand was compared with Waring

Blendor results, a more time-consuming process recommended in tentative standard methods.

Disintegration of the materials in a blender gave more accurate results than those obtained by the hand methods. The mechanical method, they concluded, should be used when accurate estimates of bacterial numbers are desirable, but the hand method is adequate for routine testing, and better than not testing at all.

Larkin and associates concluded that the high incidence of fecal streptococci on frozen fish products, possibly attributable to breeding, should make the organism easy to isolate. In addition, these organisms, although they can be eliminated by proper food processing, are somewhat resistant to heat. Consequently, they should be a more dependable indication of inadequate processing than more heat labile organisms.

Antibiotic Residual in Milk Detected More Precisely

A modification of the standard method for detecting lower level antibiotic residuals in milk was offered by Robert L. Morris, M.S., and Josephine Cerny, chief and associate chemist, respectively, of the Iowa State Hygienic Laboratory, Iowa City.

Economic losses to the dairy farmer resulting from acute and chronic mastitis in his herds have stimulated widespread use of antibiotics and better sanitation and handling practices, they said, in pointing out there has been a resulting improvement in the quality of milk as well as a reduction in the incidence of mastitis. Proper laboratory and field controls can assure antibiotic free milk, they maintained.

Morris and Cerny stressed that there is some medical opinion that continued use of low-level antibiotic residuals in milk and other foods

can result in resistances and possible allergies in the consumer, and impair the use of antibiotics against infections.

The bacterial inhibitory influence of antibiotics at the levels detected by this test casts considerable suspicion on the authenticity of standard plate counts obtained on milk samples containing demonstrable antibiotic residuals, they stated.

Morris and Cerny found that antibiotic residual tests using the technique described in the Standard Methods for the Examination of Dairy Products, 10th edition, gave nonprecise, low-level results and sensitivities to only 0.1 unit of penicillin per ml., a level which reportedly appreciably retards acid production in the manufacture of cheese. Such lack of precision in the lower levels of the standard methods test, they said, limited its value.

The modification of the antibiotic residual test consists mainly of the use of 2 one-half inch filter paper discs instead of a one-fourth inch disc.

The new double disc method is sensitive and precise to at least 0.01 unit of penicillin per ml., while the one-fourth of an inch disc procedure loses precision below 0.1 unit per ml., they observed. Penicillin ointment was used for this test.

Morris and Cerny observed that the double discs absorb about 10 times the milk volume as compared to the one-fourth of an inch discs, a factor they believed largely responsible for the greater precision. Also, it is reasonable to assume, they said, that the top disc deters evaporation of the absorbed milk and allows more complete diffusion of the sample into the agar.

They found that the large-disc modification is quite sensitive to other antibiotics and readily detects their presence in the low concentrations.

The double disc test is sensitive to low concentration levels of seven different commercially available bovine mastitis antibiotics containing such

sources and an unbiased estimate of coliform density, Hopkins and Schamberger said.

In conclusion, they stated that "the introduction of this new mathematical manipulation in existing water report procedures would not

be burdensome and the relatively simple method of establishing the central tendency density would justify its use." They were also of the opinion this procedure should be included in the Manual of Recommended Water Sanitation Practice.

The death of a man immediately following an automobile accident may be certified as an accidental death, although from the health worker's point of view, the accident may have been only incidental to the diseased condition of the heart designated by the pathologist as the primary cause of death, Treloar stated.

In addition, the pathologist may find that the man had cancer of the bladder which would undoubtedly have resulted in death in a very short time unless discovered and treated, and the man may have had arrested tuberculosis also, which was not a factor in the death and therefore was overlooked.

The record of this death could quite justifiably be claimed by several societies, Treloar said. The body is not only part of the wreckage of an accident, it is also "mute testimony to the wastage of rheumatic fever and heart disease, tuberculosis and cancer," all of which have contributed to the morbidity knowledge we seek.

Vital Statistics . . .

Suggests New Terminology For Causes of Death

Rewording death certificate forms so that physicians will be encouraged to report diseases rather than to indicate a single "cause" of death for statistical tabulation was the recommendation of Alan E. Treloar, Ph.D., professor of biostatistics, School of Public Health, University of Minnesota, Minneapolis.

Treloar suggested that a new and more meaningful term be used on the form, such as "terminal morbidity states" or "conterminous morbidity." The physician could, if he chose, indicate by an underline the condition or disease which he wished to emphasize.

Rates defining proportionate morbidity at time of death and expressing the number of cases of each disease state as a proportion of all deaths would be more informative and would cover disease conditions preceding death more completely than the presently used rate based on a specific cause, Treloar continued.

The prime interest of public health workers is in morbidity; their responsibilities require them to know as much as possible about the total morbidity picture in their communities, Treloar stated.

It is "our challenge to action; mortality is merely a measure of our defeat. Medical certification of cause of death is helpful in determining morbidity but as yet even

the best mortality records give only a grossly biased sample of morbidity conditions in a total community," he said. If complete morbidity data for each community were readily available, "our interest in cause of death certification would surely vanish," he stated.

Selecting the Cause

The selection of one disease or condition as the primary cause of death is an arbitrary act and is influenced by the viewpoint of the person making the selection, Treloar said. The vital statistician will seek a specific cause for statistical tabulation; each national society will contend for the assignment of each death to its particular category to add weight to its plea for funds; the lawyer will be interested in the legal aspects of death; and the insurance executive will consider the obligations of his company.

Clinical vs. Autopsy Findings

Treloar suggested that a specified cause is only one of infinite numbers of members of causal systems and that the so-called cause of death may be only one of many factors. For example, when death results from a chronic disease, the apparently clear-cut syndrome of clinical symptoms which give the internist confidence in assigning the cause of death do not always agree with the autopsy findings. The pathologist would often insist on some other entry on the death certificate if it were not already completed and filed, Treloar said.

Lowest Total Death Rate Found in Suburbs

Residents of metropolitan rural areas have a lower total death rate, on the whole, than the population of urban or nonmetropolitan rural areas, although the mortality experiences of different age groups vary.

Although they enjoy the most favorable mortality experience, suburbanites of the metropolitan rural counties, combining the advantages of urban and rural life, lose their advantage by middle life. Factors related in some way to the urban aspects of their lives seems responsible for this shift.

These inferences were drawn from a 1949-51 study of differential mortality according to the degree of urbanization in New York State (exclusive of New York City). The findings were reported by Elizabeth Parkhurst, M.S., biostatistician, New York State Department of Health,

certain *Euglena*. An excessive number of ciliates, he said, indicates a high bacterial population, which in turn means organic contamination.

Examination of slides at a magnification of about 430 diameters also points to the speed and stage of oxidation of organic matter to inorganic ions in the water. Large numbers of free living bacteria and *Zooplca ramigera* respectively denote initial and active stages of oxidation; fewer bacteria but many green flagellates and some ciliates, oxidation nearly complete; and great quantities of nonflagellated green algae with some ciliates and stalked bacteria, complete mineralization.

In concluding, Lackey emphasized the need for caution in interpreting such data in view of the lack of information on the ecology of many micro-organisms.

Problem of Fluid Samples Solved by New MF Test

A delayed incubation procedure, using the membrane filter, was suggested by four Public Health Service bacteriologists for examining the coliform content of water when shipment of refrigerated fluid samples is impossible or impractical.

Many laboratories serving large geographic areas have been unable to comply with the recommended 12-hour limit for commencing bacteriological examination of relatively pure water samples, maintained between 6° and 10° C., they explained.

Reporting the procedure and the trial results were Edwin E. Geldreich, M.S., Paul W. Kabler, M.D., Ph.D., Harold L. Jeter, M.A., and Harold F. Clark, M.A., all with Water Supply and Water Pollution Control Research, Robert A. Taft Sanitary Engineering Center.

The new procedure permits the bacterial examination to begin at the time of collection, they reported.

An appropriate quantity of water is filtered through the membrane at the sample collection site, and the

membrane is placed on a preservative medium. The individual petri dishes are wrapped in Parafilm to minimize evaporation and are shipped, unrefrigerated, to a laboratory for completion of the bacterial examination.

Isolating the organisms on a solid surface removes the possibility of coliform increases by cellular multiplication, and each cell theoretically becomes a countable colony, they said. Other advantages named were decreased weight per sample, small size, low cost of sample container, and transportation to the laboratory by first class or air mail without refrigeration.

Test Results

In testing the new procedure, coliform densities in water samples estimated after storage on the MF preservative medium at room temperature (13° to 32° C.), and at 35° C. for 24, 48, and 72 hours were compared with the standard methods MPN determinations on liquid samples stored at 5° C., 13° to 32° C., and 35° C. for the same time periods. Both were compared with results from an initial 5-tube, 3-dilution MPN test.

Samples were taken from 6 sources, 3 rivers, 2 farm wells, and a lake. Three samples from each source were examined in a winter and a summer series.

The preserved MF coliform counts at room temperature, they found, indicated good agreement with the MPN densities in liquid samples stored for 24 hours at 5° C., but they tended to be lower than the initial MPN.

The preserved MF results at room temperature and at 35° C. were superior to the MPN procedures on liquid samples stored more than 24 hours at the same ambient temperatures, they reported.

The MPN coliform counts on liquid samples held at 5° C. for periods up to 72 hours were quite variable, they said, but they more closely approximated the initial MPN results than those for samples stored at the higher temperatures.

Baltimore Coliform Count Uses Geometric Mean

The geometric mean is a more accurate measure of the density of coliform organisms in water supplies and streams than the arithmetic mean, or average of daily counts, stated Edward S. Hopkins, consulting sanitary engineer, and Karl H. Schamberger, principal associate engineer, bureau of water supply, Baltimore, Md.

Hopkins and Schamberger said that one or two extremely high daily counts reported during a month distort the arithmetic mean so that it does not represent general conditions for the period. Zero and a count of millions have equal weight in computing an average, they pointed out. The average, then, is not a true measure of central tendency, they said. They defined "central tendency" as "a single measure that is representative of a group of measures." This single measure could be the median, the geometric mean, or the arithmetic mean.

When bacterial counts are normally distributed, the arithmetic mean will give an unbiased estimate of coliform density and minimum variance, but one or two very high or very low counts will distort this figure so that it will not accurately represent general conditions and may give a value which is misleading, Hopkins and Schamberger said.

The geometric mean, or average of logarithmic values, on the other hand, equalizes high and low measures and is a precise measure of central tendency, they stated.

A Simple Method

Most water purification plants report daily coliform density and a monthly average of the daily figures. It would not be difficult to add to the report form a column showing the logarithmic value of the daily counts and to show the average of these values, or the geometric mean, in another column following the monthly average and its logarithmic value. This would provide a more uniform relationship between data from the same stream or data from various

Resident death rates per 1,000 population by sex and age in the urban and rural subdivisions of counties suburban to New York City, and of the total of all other metropolitan areas of New York State, exclusive of New York City, 1949-51

in the metropolitan than in the non-metropolitan rural areas, she stated.

Part of the excess mortality among older adults in the cities and suburbs may be due to higher death rates from arteriosclerotic heart disease, which were 31 percent higher in cities over 50,000 than in nonmetropolitan rural areas, Parkhurst said. However, this differential in the cause of death may reflect superior diagnosis of coronary disease in the cities, she concluded, since the death rate from all forms of heart disease was only 23 percent higher in cities over 50,000 than in nonmetropolitan rural areas and, from all cardiovascular diseases as a group, only

12 percent higher, because of lower rates for vascular lesions and nephritis.

Seeks Constructive Ideas For Mortality Studies

What are the specific needs not now being met that should be met by cause-of-death statistics?

It is high time that less attention is paid to what is wrong with cause-of-death statistics and more work devoted to constructive answers to this question, said Iwao Moriyama, Ph.D., chief, Mortality Analysis Sec-

tion, National Office of Vital Statistics, Public Health Service.

Once the needs are determined and agreed upon, the next step will be to examine the elements that go into mortality statistics. It should be possible, he said, to alter one or more of the following: the basic medical information supplied by the physician, the method of reporting, the classification list of diseases, and the method of selecting causes to be tabulated.

The increase in public health importance of the chronic diseases is one reason for the growing indication of inadequacy in current mortality statistics, Moriyama implied. He pointed out that the traditional compilations, despite their limitations, have proved of value in the past when public health was concerned chiefly with infective diseases.

The nature of mortality data is one factor limiting the uses of mortality statistics, according to Moriyama. Cause-of-death statistics are descriptive of the illnesses and injuries of the population that has died, but they cannot serve as reliable indicators of morbidity unless the fatality rates for the different morbid conditions are known or are known not to vary greatly from time to time or place to place, he noted.

Moreover, the underlying cause of death—the basis for current compilations of mortality statistics—may be a disease or condition not present at the time of death. Hence, it is difficult to see how the concept of the underlying cause of death fits within the framework of any morbidity survey, he declared.

For the study of morbidity, Moriyama suggested that it may be useful to obtain information on all the diseases afflicting the deceased at the time of death, with some distinction between those associated with the death and those not associated.

Quality and Classification

Another limiting factor is inaccuracy in clinical diagnoses and in reporting causes of death. Mori-

Albany, N. Y. The United States Census Bureau's identification of metropolitan districts, associated with towns of 50,000 or more, was used to distinguish metropolitan from nonmetropolitan areas.

Parkhurst said the study indicated that "the large cities appear to have evolved an environment into which children are born and grow up at no disadvantage, and even at some advantage to their rural cousins. The mortality experience of the adult population, however, is far less favorable in the cities than in the rural areas, and more so in the metropolitan than in the nonmetropolitan cities."

In rural areas, the death rate from accidents among males aged 5-14 and 15-24 years (one-half and two-thirds, respectively, of deaths from all causes) accounts for much of the metropolitan advantage.

Young Adults

In the metropolitan rural areas mortality among young persons aged 15-24 is higher than in the cities. This may be attributed to the migration of many young persons, particularly young women, from suburban and rural areas to the cities, Parkhurst stated. Since those who are ill remain at home, this factor may account for the higher death rate for

females in this age group in areas outside large cities, she said.

In suburban areas, the death rates, particularly among males, are lower than in central cities, Parkhurst said. This is probably due, not only to the higher standard of living in the suburbs, but also to the fact that the suburban population is made up of men with families. Married men as a group have a much lower death rate than the single, the widowed, and the divorced, who usually live in cities, she noted.

Older Adults

For women between the ages of 45 and 75 and for men between the ages of 55 and 75, death rates are higher

¹ Standardized, by direct method, to the age distribution of the population of New York State in the census of 1940.

"Many of the persons whom public health nurses and social workers seek to serve are patients or clients being asked to move from narrow self-contained environments into a larger cultural milieu of which scientific health practices and elaborate treatment centers are a component," Brown stressed. "How can it be hoped that persons limited by educational or social experience or by prejudice, real or imagined, will be able to make such a move without putting a severe strain on their patterns of psychological adjustment and hence on their mental health?"

They will need help, Brown asserted, but help of a kind they can accept. The public health nurse is in a strategic position to give that help, she concluded.

Interpersonal Relationships

From the mental health viewpoint, current nurses' training programs do not facilitate optimal development of the skills and experiences essential to understanding of and proficiency in interpersonal processes, according to Stephen Fleck, M.D., associate professor of psychiatry and public health, Yale University School of Medicine, New Haven, Conn.

Fleck, in his contribution to the discussion, added that the public health nurse needs to discern and understand quickly the character of interpersonal relationships in groups of people, in addition to prompt recognition of individual maladjustment. Preparation for this must pervade the entire training program, undergraduate and graduate, Fleck said.

The role of the public health nurse in mental health is determined by administrative planning and action, according to Mary King Kneedler, R.N., B.S., M.A., chief of the public health nursing section of the North Carolina State Board of Health, Raleigh, N. C.

Kneedler stated that this includes the setting of objectives and the course of action; coordination of personnel within the agency and coordination of the program with that of

other agencies involved in a mental health program; and staff education in the area of mental health.

Nurses Evaluate Own Role In Adult Home Program

Forty Kansas nurses expressed varying feelings about their part in the licensing of adult boarding homes and made a number of suggestions for improving the program, reported Lucille E. Tracy, R.N., B.S., director, public health nursing, Wichita-Sedgwick County Department of Public Health, Wichita, Kans. Tracy summarized representative replies to an opinion poll of 72 public health nurses, supervisors, and staff nurses as follows:

Favorable Effects

From the standpoint of care of the boarding home residents, the nurses felt that the licensing program had improved the safety of medication and other treatments.

Home administrators have learned the professional nurse's concept of nursing as the art of giving care and medications to the sick under medical supervision. Administrators have been taught to observe patients professionally and to improve the records of their observations.

They have also introduced additional safety measures such as hand rails in tubs and showers and on stairs.

Those in charge of patients have been helped to see emotional as well as physical needs of patients. More thought has been given to rehabilitation and more activity has been provided for residents.

The support from the local health agency has given administrators more confidence, an opportunity to discuss problems, and an awareness that others are interested in their work.

The area of supervision for nurses has been extended by this experience. They have gained insight into the problems of the aging, the nurs-

ing needs of elderly sick persons, and of the impact of family relationships and their effect on older persons. They have also learned what happens to elderly persons who have no family.

Nurses have increased their skills in teaching, writing reports, interviewing, and counseling and have applied safety measures in public health nursing. Working relationships between the health department and other welfare agencies have been improved. Opportunities for both group and individual teaching of nursing procedures and techniques have been ample.

The need for standards for nursing homes is gaining recognition and acceptance in the community. Also, local health and welfare departments have been given opportunities through this program to work together on improvement of mental health.

Unfavorable Effects

The licensing nurse represents an authoritative and judgmental figure to the nursing home administrator, who may find it difficult to recognize the nurse in a guidance role. A great deal of time and careful work is needed to change the administrator's viewpoint so that the public health nurse will be consulted and will be thought of as an ally and not as an investigator or law enforcement agent.

Acting as an evaluator is counter to the nurses' principle of accepting people as they are and of working on problems which they regard as of foremost importance. Overlapping of authority has created some confusion for both nurses and administrators. Some nurses are reluctant to work with welfare workers, and others feel that their evaluations are not given enough recognition by the State health department.

Suggestions for Improvement

Careful consideration should be given to the question of whether or not the nurse is serving in her best capacity when she acts as an evalu-

yama cited several studies which he said have shown lack of agreement between causes of death based on clinical information and causes based on autopsy information, particularly for the so-called clinical diseases, such as hypertension and diabetes.

There is no question that there is room for improvement in the quality of medical certification, he admitted. However, he considers it "altogether unreasonable to expect absolute precision in diagnoses involved in death." The most that can be expected from cause-of-death statistics is that they reflect as accurately as possible the average current medical opinion based on all available information, he said.

The classification scheme, which largely determines how diseases are grouped and how much detail can be obtained, might be considered a third limiting factor, Moriama indicated. Certain sections of the classification list are recognized as "not particularly satisfactory," he pointed out. With reference to the section

on circulatory diseases, he urged more studies of the problem of the cardiovascular-renal diseases in preparation for the eighth revision of the International Lists in 1965.

A fourth factor definitely limiting the usefulness of mortality statistics is the method of classification. The underlying cause-of-death concept has had great utility, but not all needs for cause-of-death statistics are concerned with the underlying cause, he stated. For example, there are expressed needs for data that would describe a disease complex or the relationship between the diseases that led to death, and there is a need for information on the therapeutic misadventures and untoward effects of drugs.

Moriama mentioned that experimental studies on the tabulation of multiple causes of death have been conducted, but that as yet little or no attention has been given to the uses and meanings of such tabulations.

terms of behavior, the nurse's own included, are conditioned by educational, economic, religious, racial, national, and geographic backgrounds, Brown declared.

Recently, she reported, schools and organizations have become increasingly aware of the potential application in the health field of this type of knowledge. To this end, the Russell Sage Foundation, among other organizations and individual scientists, are trying to provide a literature designed for use by public health workers and by schools training health workers.

Specific to Situation

"The larger question remains," she went on, "of how the facts about social and cultural factors and their interpretation can be made specific enough for application in a wide variety of clinical or health-teaching situations throughout the country."

"What is needed," she said, "are data that furnish the worker with some immediate guide to attitudes toward sickness, medical personnel, clinics, hospitals, health as a positive goal, which may be expected in a particular type of patient, family or community; data that provide clues about how a relationship could be established that might otherwise be impossible."

Before literature of such dimensions is available, Brown said, years of collecting, analyzing, and interpreting of materials will be required. However, she pointed to important beginnings that have been made; for example, the current study of all patients using the comprehensive general clinic of the Denver General Hospital. One-third of the patients are of Mexican or Spanish-American descent. A sample of the clinic patients will be followed into their homes and community while a study of physician-patient relationship is conducted at the clinic through the medium of a oneway screen. This study may give some indications of the particular social and cultural factors significant in the therapeutic process, she said.

Public Health Nursing . . .

Studies of Attitudes May Shape Training

Public health nurses, particularly those concerned with mental health, will have a valuable instrument in studies which interpret data pinpointing individual as well as group attitudes, in the opinion of Esther Lucile Brown, Ph.D., an executive of the Russell Sage Foundation, New York.

From such interpretive studies nurses may learn how attitudes can be altered for constructive purposes.

In her discussion of the contribution of the behavior sciences to understanding in public health nursing, Brown raised two fundamental questions:

How can understanding by the public health nurse of the patient and his needs, or the family or community and its needs be developed?

How can such understanding be used for therapy, prevention of mental as well as physical disease, and teaching of positive health?

The gains made in understanding the personality structure by psychiatry, psychology, and the social sciences have not yet been sufficient to equip the public health nurse entirely to meet problems arising in the treatment of persons who have different linguistic, social, and economic backgrounds, she said.

If the nurse is to view the patient in relation to his family or community matrix, much more must be known about how attitudes and pat-

tural backgrounds. All but three were staff level nurses.

Group Education

Leadership training focused on parent group education, the objective being to help parents become better parents rather than better group members. It is a complex method, Auerbach stated. Leadership cannot be acquired quickly or established by resorting to easy devices. The group leader develops the discussion from the experiences of the parents as they look at their family problems with their peers.

The decision to prepare nurses for the application of discussion methods to work first with parents of growing children, and only thereafter with expectant parents, was made to see whether they could acquire leadership skills more easily in an area in which they had not functioned before, Auerbach said. Once the nurses felt comfortable when using the newly developed techniques, they might apply them flexibly elsewhere, it was thought.

Because the program was a pilot study and because the training group was a small one, the results are only suggestive of what further research may find.

On the significance of the nursing program for nursing education—suggesting the possibility of changes in teaching methods, in selection of students, and in curriculums of nursing schools, Auerbach stated:

"The study suggests chiefly that these nurses were not as adequately prepared as might have been expected with regard to certain important aspects of child development and parent-child relationships which, certainly, pervade all phases of their work, whether they are working with parents in groups or seeing parents and/or children in clinic conferences or home visits."

The skills of parent group education based on the discussion method can be acquired, with special training, by public health nurses, but not all members of any professional group may be expected to lead groups with equal effectiveness,

Auerbach remarked. As a professional group, nurses brought to this work certain assets and limitations, out of their general professional training. Vocationally, they are in a strategic position to serve as leaders of parent groups.

Assets, Liabilities

Among the assets cited by Auerbach were the following: thorough knowledge of certain phases of individual growth and family needs, particularly the physical side in health and in illness; sympathy for children's needs; close contact with the community's families; knowledge of community resources for personal and health services; some knowledge of the group discussion method; conscientious and responsible attitude toward acquiring new skills and toward using themselves in a disciplined, professional way; acceptance of supervision, including being observed in action.

Among the limitations, she listed: lack of sufficient knowledge in child growth and development and in family relations; insufficient knowledge of dynamics of behavior, individually and in groups; limited diagnostic awareness of pathology in child behavior and parental attitudes; little familiarity with cultural variations in child care attitudes and practices; little practical

knowledge of group techniques; limited knowledge and acceptance of their active role in individual supervisory conferences.

She added that the findings did not throw any additional light on the selection of trainees although correlations of personality trends and performance ratings did indicate that the more authoritarian the nurse, the less effective her teaching by the group method. Auerbach also remarked that study is needed of intelligence levels, flexibility, emotional maturity, and other personality factors.

For new programs of this type to be effective, she concluded, nurses need staff support in recruiting interested parents and in arranging their workload so they can give sufficient attention to the organization and conduct of their groups.

To consolidate the program described, New York State has a threefold program now in progress, Auerbach reported. This includes supervision of the first group of nurses in the conduct of second parent groups and antepartum groups, a new complete project for public health nurses, and a training program for hospital nurses for work with groups of expectant parents. The research project is being continued, she said, to help evaluate the two new training projects.

Physician Distribution . . .

Low-Income, Rural Areas Report Loss of Physicians

The difficulties faced by rural communities in their attempts to attract and keep physicians will become more serious in the future, stated Milton Terris, M.D., M.P.H., and Mary A. Monk, Ph.D., of the University of Buffalo, Buffalo, N. Y.

Dr. Terris is assistant dean for postgraduate education and associate professor of preventive medicine and public health, School of Medicine. Dr. Monk is research associate in postgraduate education and instructor in medical statistics, School of Medicine, and lecturer in social psychology, College of Arts and Sciences.

The national trend in the distri-

ator. If she is, she needs continued help to accept and fulfill that role.

Demonstration days, when administrators can show each other special rehabilitation techniques would be helpful.

Criteria should be developed to evaluate the mental capacity, ability, skill, and understanding of the prospective boarding home administrator.

More conferences are needed between agencies and administrators working on specific problems.

Presenting standards to the evaluators before they are presented to the administrators would help to eliminate many of the frustrations which develop when the standards are presented to the administrators.

When standards are adopted they should apply for a reasonable length of time.

All boarding homes should be licensed, including private boarding homes.

Kansas Nurses Participate In Adult Home Program

Public health nurses are taking an important part in the adult boarding home program in Kansas, but they still need help in adjusting to the role of evaluator, according to Roberta E. Foote, R.N., M.A., director, public health nursing, division of local health services, Kansas State Board of Health, Topeka, Kans.

When Kansas gave health departments an official part in licensing nursing homes in 1951, public health nurses were reluctant to participate in the program, Foote continued. They did not wish to be regarded as inspectors.

Nevertheless, the nurses believed that they should participate in formulating standards for care and treatment of ill or elderly persons, in helping operators of boarding homes care for their patients, and in evaluating services and structures, Foote stated. They also felt that it would be good nursing practice to care for and to champion the cause of elderly people who are helpless

or ill and that, by visiting nursing and boarding homes, they could teach nursing procedures to the administrators. However, in describing their part in the program, they changed the word "inspection" to "evaluation."

Standards of Care

Although elderly and ill persons are only a small part of the Kansas population, they are helpless as individuals and have many physical handicaps. Public health nurses can do much to close the gap between knowing what should be done and what actually is done in caring for them, Foote asserted.

Nurses have always observed or "inspected" symptoms and environment and have learned to evaluate the work of students and staff in a cooperative and constructive spirit, and "we can and do evaluate the adult boarding homes in the same spirit," Foote said.

Many nurses are overcoming their fear and dislike of appearing as witnesses at formal hearings, she stated, although they do everything they can to prevent court hearings. They know that most administrators of boarding homes are as interested as the nurses in giving good care to the residents and, before court hearings are held, the nurses ask the licensing agency to arrange for informal conferences between the administrator and the licensing agency to find ways to help the administrator meet the agency's standards for the homes.

Concern for the improvement of standards of institutional care has increased in the past 10 years, Foote stated. Before 1947, only 4 of 46 States reported legislation on institutions for older people, whereas during 1947-50, 18 States passed this type of legislation.

At times it has seemed as if "the licensing programs were overshadowing everything else," but "the facts do not bear this out," Foote stated. It is estimated that in the agency having the largest number of homes under its supervision, the li-

censing program took only about 2 percent of the nurses' time and less than 2 percent of their visits. Lucille Tracy, of the Wichita-Sedgwick County Health Department, is the public health nursing director of this agency. Her summary of the opinion poll of public health nursing personnel precedes this presentation.

As a result of the licensing program, better teamwork has developed within the health department and between the health department and other agencies, she concluded.

New York Nurses Train To Lead Parent Groups

When the Child Study Association of America, at the request of health authorities, undertook to train 15 public health nurses as leaders of parent discussion groups, it embarked on pilot research which could influence the content of public health nursing education. Whether the findings have any bearing on nurses' training, said Aline B. Auerbach, depends on how extensively one defines the goals in nursing education.

Mrs. Auerbach, director of the association's leadership training department, described the experiment begun in March 1954 for the New York State Health Department with the sponsorship of the Children's Bureau of the Department of Health, Education, and Welfare.

The project consisted of 13 weeks' preliminary training in the content of parent group education and techniques of leadership, followed by work in the field under health department auspices and supervised by the association's staff.

A faculty representing the disciplines of psychiatry, research and clinical psychology, education, and cultural anthropology participated in the intensive training program of theory, observation, and group seminar work. A research advisory committee followed progress of the project and evaluated the responses of the nurses to the program. Trainees came from different cul-

Council's Efforts Improve Physician Distribution

The Virginia Council on Health and Medical Care can almost guarantee a physician for a community if the community wants one, needs one, and is willing to work for one, according to Edgar J. Fisher, Jr.

Fisher, director of the council, reported that success of the organization's physician placement service can be attributed largely to its background work with medical students and interns. Since the service began in 1950, 120 physicians have been placed, significantly improving the physician distribution problem in the State as well as providing physicians for smaller communities, Fisher said.

The Virginia council has directed primary attention to the needs of the Medical College of Virginia and the Medical School at the University of Virginia. Support has been given to better salaries for professors, training facilities, and other needs. In addition, 50 medical, 4 dental, and 74 nursing school scholarships are offered annually to students pledging a year of rural practice for each year the scholarship is held.

Rotating Intern Program

Fisher said that the rotating intern program which the council helped promote assists rural hospitals in meeting personnel shortages as well as providing valuable training. The interns are assigned to 6 small hospitals in outlying communities for a 2 to 3 month tour of duty under the supervision of their medical school professors, who make periodic visits to the hospitals.

Junior medical students each fall receive from the council a letter that explains the placement service and offers material descriptive of rural practice. Senior students receive a reminder of the service and, after they become interns, they receive another letter from the council which includes a questionnaire to be returned if the student desires to be placed on the list of available candi-

dates. Out-of-state school students also are assisted to find rural practices. At monthly seminars held at the University of Virginia, rural practice is informally discussed with students.

Services Mutual

"We do all we can to make it easy as possible for a physician to find the type of practice he is looking for," Fisher said. The physicians are sent lists of communities needing physicians and the communities are provided with lists of general practitioners and specialists seeking placement and usually the type of opportunity or skill sought can be provided.

Community requests for help are investigated by the council to establish the need and ability of the area to support a physician. Sometimes requests are turned down but after a request has been cleared, a personal visit is made to the community and it is instructed in the methods of seeking a physician. Experiences of other areas are shared with it, methods of financing clinics are explained, and ways in which to make a community attractive for a physician are detailed.

"The council will help a community to the extent that the community wants to be helped," Fisher stated, pointing out that there were 50 communities then seeking general practitioners and there were 80

available. Specialists were called for in 24 places and 100 were listed as available.

Recently Virginia has set up a dental placement service, as the need for dentists is considered even more acute than the need for physicians. A clearinghouse program for medical technologists is in the planning stage.

Human Relations

Fisher said the program brought out some interesting facts in human relations. Young physicians frequently fail to reply to correspondence, fail to keep specific appointments with communities, and often consider they are doing the community a favor when they locate. Many fail to put roots into the community of choice, and then blame their wives when problems arise. Often they are unappreciative, or unaware, of what the community has done to help them get started.

The attitude of some communities is also disturbing, Fisher reported. Some fail to live up to promises made the new physician; many do not consider his time and his privacy. In many areas, the new physician is called in only for emergencies and night cases. He advised communities to avoid gossip and unjustified criticism of the physician and his family, to respect posted office hours, to avoid raising the price of property a physician seeks to buy.

Trends in Nutrition . . .

Better "Convenience Foods" Predicted for Future

The housewife will have less to do and the food processor more in the preparation of foods for the table.

This was the prediction for the future made by Horace K. Burr, Ph.D., and Everett R. Wolford, of the Western Utilization Research Branch of

the Agricultural Research Service, United States Department of Agriculture.

At least some segments of the population will benefit nutritionally, they said, in reviewing the trend toward developing more and improved convenience foods. The wider the variety of foods available in easy-to-prepare form, the more varied will be the diet of the family dependent

bution of rural physicians is emphasized by the findings of a study in the 32 counties of western New York comprising the Buffalo, Syracuse, and Rochester regions, Terris and Monk said.

Trends in population-physician composition of the population of the United States

Year	Rural population (percent)	Rural physicians (percent)
1906-----	53	41
1929-----	48	31
1940-----	43.5	20

That rural areas tend to lose physicians in periods of prosperity and to keep them in periods of depression is apparently one of the laws governing the distribution of physicians in the United States, Terris and Monk continued. According to Mountin and Pennell, between 1923 and 1931, a period of prosperity, the rural population of the United States increased 5 percent, whereas the number of physicians in these areas decreased more than 17 percent, they said. The figures for 1931-37, a period of depression, were 6 and 2 percent, respectively.

Age Distribution

In upstate New York in 1930, the

age distribution of physicians was essentially the same in all communities, regardless of size; in 1930, physicians in rural areas were considerably older than physicians in urban areas, Terris and Monk stated. This finding is in sharp contrast to the findings of other studies, they pointed out. It may be accounted for by the influx of new graduates into rural areas during the depression years; by the number of young physicians, many of them local residents, graduating each year from the three medical schools in the region studied; and by the fact that the favorable economic position of upstate New York enables rural areas to attract and hold young and middle-aged physicians, they said.

Specialization

Terris and Monk were of the opinion that "despite certain evils of specialization . . . we believe the growth of specialization has been a most important factor in improving the quality of medical care." Some of the differential in the quality of available medical resources between the large cities and the smaller centers is diminishing. In only 10 years, the percentage of full-time specialists in all areas of the three regions as a whole has increased over 50 percent, from 22.3 percent in 1940 to 36.8 percent in 1950. In rural areas, the percentage of specialists

rose from 2.5 percent to 6.4 percent, although, in comparison with the urban communities, the percentage of full specialists remained quite low. Sooner or later, the emphasis of postgraduate education will have to take cognizance of these changes.

Income

In the three large cities in the study area, the physician-population ratio increased for the city as a whole and for the middle-income and high-income neighborhoods. For the low-income neighborhoods, however, there was a decrease. From 1930 to 1950, the decrease was 7 percent in Rochester, 14 percent in Syracuse, and 24 percent in Buffalo.

"The widening gap in physician-population ratios between low-income and high-income areas of large cities is apparently a recent phenomenon, at least in the three cities studied," Terris and Monk stated. No ready explanation is available, they said, although the war may have been a factor from 1940 to 1950, when physicians found it easy to change locations.

"It would be of considerable interest to study the situation in other large cities in order to learn whether the decline in the number of physicians in low-income neighborhoods is a general phenomenon and to determine the periods in which such declines occurred," they concluded.

Percentage of physicians in the Buffalo, Rochester, and Syracuse regions in 1930, 1940, and 1950, according to number of years after graduation

Size of community	Years since graduation								
	1930			1940			1950		
	0-10	11-30	31 and over	0-10	11-30	31 and over	0-10	11-30	31 and over
Under 2,000-----	19.1	32.0	48.8	31.3	27.8	40.9	14.7	55.3	29.9
2,500-9,999-----	15.5	37.3	47.2	29.2	33.7	37.1	15.0	52.9	32.1
10,000-49,999-----	23.1	42.3	34.6	24.6	44.1	31.3	14.2	57.5	28.4
50,000-99,999-----	25.6	44.6	29.7	25.1	50.2	24.7	15.3	59.9	24.7
100,000 and over-----	27.0	48.6	24.4	24.8	46.7	28.5	21.2	51.1	27.7
Total-----	23.9	43.5	32.6	26.2	42.2	31.6	18.2	53.5	28.3

The first test showed that both research and control groups fell below the standard recommended for daily intake of milk, eggs, citrus fruits, other fruits, butter and fortified margarine, Irish and sweet potatoes, green leafy vegetables, non-leafy vegetables, whole grain and enriched products, and lean meats. The highest intake was in meat—one class consumed 46 percent more than the recommended daily dietary allowance. The lowest intake was not only in green vegetables but in butter and fortified margarine, milk, and potatoes as well.

Some of the teachers planned study trips to city markets, followed by vegetable-tasting parties to get at the problem of changing the diet pattern. The next year the problem was approached through an animal-feeding demonstration with guinea pigs. Another way of meeting it was to plan meals from menus of different places.

When one teacher learned that few of her students had ever been to a restaurant, she decided that actual experience with money and transportation, good manners and good grooming, and knowing why certain foods were chosen were essential to help boys and girls hurdle the transition from 25-cent plate lunches to the selection of meals in high school cafeterias and public eating places.

From this and similar experiences, two filmstrips were later prepared. One is entitled "Eating Out."

Measured Gains

At the beginning of the study only 53 percent of the research group and 35 percent of the control group met the recommended dietary allowance in green leafy vegetables. At the end of the second year there was only a 19-percent gain for the research group and a 13-percent gain for the control group.

At the close of the second year the children who participated had met or surpassed the recommended daily allowance in 6 food groups. The control group met or surpassed the standard in 2 food classes only.

At the end of the study the research groups had met or surpassed the food standards in 3 food groups and had made gains in 7. The greatest gain, 21 percent, was in butter and margarine intake. The control groups met or surpassed the recommended allowances in 1 food group and made gains in 3 food groups, including the fats.

Over the 3 years, the sixth graders showed an improvement in food intake in every group except non-citrus fruits and nonleafy vegetables. The sixth grade controls improved their food intake only in meat, fats, and potatoes.

Results of the Ohio education and hygiene test showed the groups in the research schools to have a broader and more scientific knowledge of food than those in the control schools.

The nutrition information test showed an equality in medians between the research and control groups at the start, 43 for both, but 3 years later the medians were higher—61 for the research group and 53 for the control group.

The above average scores on reading, language, and social studies for the research group allayed all fears teachers had expressed about the amount of time they spent on nutrition education.

Chronic Malnutrition Pictured in Mexico

Evidence gathered from malnourished patients at the Hospital de Enfermedades de la Nutrición, Mexico City, Mexico, D. F., suggests that inadequate nutrition leads to lowered cellular activity: Cells are unable to use the indispensable vitamins and hormones which promote cellular metabolic activity with the result that glands, lacking normal stimuli, atrophy.

The director of the hospital, Salvador Zubirán, M. D., said that the hypothesis of decreased activity in the entire endocrine systems is supported by clinical, histological,

endocrine, and dietetic studies on 543 patients between ages 20 and 60. Recovery of patients placed on an adequate dietary regimen and concurrent work with children at the Hospital Infantil de Mexico also support the theory, even though experimental evidence is still needed, he added.

The nutrition studies have led to the concept of a chronic deficit in every component in the diet. The Mexican investigators have termed the multiple deficiency "chronic malnutrition" to denominate the complex clinical manifestations found in the malnourished patient suffering from a combination of pellagra, pellagra sine pellagra (when there are no dermatological manifestations), beriberi, hypoproteinemia, nutritional anemia, and ariboflavinosis.

"We know now that the endocrine disturbances have great significance and should always be investigated in malnutrition because they have at least the same importance as the alterations in other organic functions and are more important and more significant for the life and well-being of . . . patients than the dermatological alterations so fully described by others," he stated.

He explained that although nutritional deficiency is common to Mexico and the rest of the Latin American countries, the people show no signs of deficiency in clinical examinations or in laboratory tests. They are apparently healthy and capable of much physical exertion. Insufficient intake is manifest only in a decrease in mental capacity, lack of ambition, short stature, and in low resistance to infection. Otherwise, their bodies are adapted to a diet inadequate in calories, vitamins, and proteins especially. Any slight reduction in the usual intake or any increase in metabolic requirements, however, easily upsets their equilibrium.

Chain Reaction

A diet deficient in every respect affects each cell in the organism and the organic functions, leading to

on the employed housewife to prepare the meals. Improved color, flavor, and stability, the goals of the processing industry, are usually accompanied by improvements in handling, processing, and storage procedures which largely preserve the nutritive values of the fresh commodity, they stated.

They also felt that the cost of these foods to the groceryman and the consumer would decline as volume expands and competition thrives.

Already observed is the trend to variety in household menus. They pointed out that housewives can now obtain pre-prepared Italian, French, kosher, Chinese, or Mexican dishes although they would have great difficulty in obtaining from grocery shelves the ingredients to prepare these dishes themselves.

Much research in convenience foods is conducted by the Agricultural Research Service, particularly in those foods vital to the armed services.

Burr and Wolford said they expected that in the near future the housewife will be able to buy satisfactory dehydrated foods, like onion flakes, from her grocer. These are now being used successfully by manufacturers of soups, stews, and casserole dishes. Dried eggs and egg fractions and dehydrated diced potatoes satisfactory to the consumer also are to be expected.

New Products

Food processors are beginning to apply vacuum puff-drying techniques to fruit and vegetable juices and may possibly adapt them to milk and other liquid or pureed foods, they stated. Among the most promising today are:

A stable instant orange juice powder with a storage life in excess of 6 months at 100° F. with very little change in flavor or vitamin C content and only minor losses of carotene. Other citrus fruits will be processed similarly.

A tomato juice powder which can be reconstituted into an excellent juice or can be used as a substitute for tomato paste for use in the prepa-

ration of dry mixes for tomato aspic, spaghetti sauce, or tomato soup. Losses of ascorbic acid during storage of the tomato powder are negligible when packaged in vacuum or under nitrogen with an inpackage desiccant, not more than a few percent loss in 6 months at 100° F. In contrast, under the same conditions canned tomato juice may lose 40 percent of its ascorbic acid, and a high solids canned tomato juice concentrate may lose 80 to 90 percent.

Dried and Concentrated Foods

Mashed potato powder appeared on the retail market in 1947. At that time it met with limited consumer acceptance, they reported, as it developed a brownish offcolor and a slightly scorched flavor during storage. The product has been improved until it is virtually free of this defect. A second defect, a pasty or rubbery texture in the reconstituted potatoes, they stated, will not appear if directions are followed carefully.

Dehydrated milk products have been improved and are finding consumer acceptance, they reported.

A new technique using the enzyme glucose oxidase which converts the glucose in whole egg and yolk into gluconic acid has eliminated the objectionable browning of dried egg products and greatly increased their storage stability from a flavor standpoint, they disclosed. They said that the dried whole egg solids produced by the new process are about 50 times as stable as the World War II product, and if properly packaged the new product should make highly acceptable scrambled eggs even after a year in storage at 100° F. At the same time, extensive research in pasteurization has resulted in general acceptance of methods to reduce active microbial contamination of egg solids.

Nutrition Education Alters Students' Menu Patterns

In Kansas City, a natural locale for steaks and beef roasts, nutrition experts suspect that green leafy vege-

tables are seldom part of the family meal.

At least, the food habits of young teenagers indicate that the family pattern of eating may emphasize meat to the neglect of green vegetables. Some food habits, however, have been favorably influenced by the emphasis given to nutrition education in the public schools. Other values of the program may not be evident until these children have grown up and have homes of their own.

Patricia Ruth O'Keefe, Ph.D., director of health and physical education for Kansas City schools, told about a recently completed study undertaken to measure what boys and girls know, as well as what they do, about nutrition. She said that the statistical data will be found in a subsequent report.

Patterned on the nutrition studies made in Ascension Parish, La., by Dr. Eugenia Whitehead, University of Iowa, the study centered around the individual teacher's creative ability to relate nutrition education in her classroom to other subjects and to community activities. The experiences planned for the children were as limitless as the initiative and interest of the teacher. Materials and help were given, and parents, principals, and educators were consulted for exchange of ideas and information. Dr. Whitehead was co-director of the study.

Creative Education

Sixth and seventh grade children in 2 schools were tested along with the same grades in 3 other schools, but the children in the first 2 schools were not aware they were functioning as a control group. Both control and research groups were followed for 3 years and tested at intervals. When they reached the eighth grade, research groups showed evidence of holding their own and making better nutritional progress than the control groups.

All six participating teachers developed their own programs after the first food appraisal revealed the areas needing improvement.

males (the final count was 280 males and 297 females); age distribution as comparable as possible to the general community.

The investigation included a 7-day recorded food intake and general food history taken by a nutritionist; clinical history including general medical and detailed systems history; a physical examination; and laboratory procedures including: blood hemoglobin, serum protein, sedimentation rate, packed red cell volume, blood glucose, ascorbic acid, vitamin A, carotene, non-protein nitrogen, free cholesterol, and cholesterol total, leukocyte count with cell differential, erythrocyte count, and serologic test for syphilis.

Also included, they added, were urine glucose and albumin tests, chest X-ray, bone density determination, and vaginal Papanicolaou smears for all female patients.

This report, Chope and Breslow said, is only one phase of this broad study. It provides an approach to the part which preventive medicine may play not only in the prevention of deaths from heart disease, neoplasms, and central nervous system disease, but also in promoting a fuller life for the aging.

Claims Food Advertising Has Adequate Policing

Refutation of the contention that food and nutrition advertising is inadequately controlled was offered by Paul J. Cardinal, B.S., vice president in charge of the vitamin division, Hoffmann-La Roche, Nutley, N. J.

The Federal Trade Commission and the Food and Drug Administration, he believes, are effective deterrents to serious abuses of public credulity. The advertiser, he added, may also have to remember other Federal agencies, such as the Treasury Department if he is selling an alcoholic beverage. He is mindful also of State laws and of organizations such as the better business bureaus.

These, along with an increasingly well-educated public, remove the need for additional voluntary tribunals, he stated.

Cardinal pointed out that in the \$8 billion advertising business, most advertisements are developed by experts who, through survey and test campaigns, keep alert to the public attitude. Nutrition workers will get results from justifiable criticism by writing direct to advertisers, he maintained.

Life is far from light for the person who has final responsibility for the claims to be made in his com-

pany's advertising, he said, and declared that the desire to be correct, accurate in scientific data, and fair is predominant. A cease and desist order, he explained, is a blight upon the company's record and as worrisome as the arrest of one's child.

The American public likes advertising, he claimed, recognizes it has contributed to high standards of living and comfort, and knows that high-pressure selling may produce some overemphasis. The public, he said, feels itself qualified to judge good from bad claims and insists it be left free to do so.

Health Services for Migrants . . .

Migrants in Colorado Get Health Services

Planning for health services for migrant agricultural workers means planning for adequate services for all residents of a community and making these services available to migrants, stated Ruth B. Howard, M.D., M.P.H., and Georgia B. Perkins, M.D., of Denver, Colo.

Dr. Howard is chief of the maternal and child health and crippled children section, Colorado State Department of Public Health, and Dr. Perkins is regional medical director, Children's Bureau, Region VIII, Department of Health, Education, and Welfare.

Health services are "available" only if they are acceptable to and meet the needs of a group, they continued. In many areas, coordination of existing services is all that is necessary to accomplish this; in other communities, new public or private services may need to be added or other services expanded during peak seasons.

Health and welfare services, they stated, must be adapted to the cultural characteristics of the migrating group and of the local com-

munity. The medical problems of migrants, although aggravated by the circumstances of their lives, are similar to the medical problems of permanent residents of a community. Migrant workers will accept health services when these services are offered in terms which they can understand, they asserted.

Also, in all places where the migrant travels or lives, health and welfare services must be coordinated. Even in local areas, groups such as the county welfare department, employers' groups, voluntary agencies, the health department, and the medical society frequently are not familiar with the resources and programs of the others. However, progress is being made toward better understanding between these groups.

Colorado Project

Howard and Perkins described a project in two large labor camps—Fort Lupton and Palisade—in Colorado for improving the quality and availability of maternal and child health and other medical services for agricultural migrants. In this project, particular consideration was given to improving communication between the migrants and local resi-

clinical syndromes in one or another system of the body, Zubirán continued. Lesions of the skin and mucous membranes are present and so are neurological, hematological, digestive, and endocrine disturbances.

When the nutritive elements are not present in amounts adequate for normal cellular life, organic combustion decreases within the cell. All of the cellular metabolic processes decrease progressively until only those absolutely necessary for life remain.

The metabolic processes are slowed, and the rate of utilization and inactivation of hormones deriving from the target glands is proportionately diminished. This decreased utilization results in a relatively high blood concentration of the hormones, leading to inhibition of the pituitary gland. Thus, the production of trophic hormones is reduced, and the target glands do not receive their customary stimuli.

The final result is a picture of panhypopituitarism resulting from the reduced amount of hormones secreted by the target glands and from the incapacity of the tissues to respond to the hormones.

Panhypopituitarism in turn leads to a dysfunction of the entire endocrine system. The gonadal functions are the first to be lost. Next, in a minor degree the functions of the adrenals and thyroid are altered. Toward the end, the endocrine functions that intervene in vital oxidation and production of energy are lost.

Histological studies of post-mortem and biopsy material obtained in 195 cases of malnutrition constantly showed atrophy and involuntary changes in the anterior pituitary, adrenal, and thyroid glands, and in testes or ovaries. Hormone determinations and endocrine function tests as well as the clinical studies showed the existence of marked hypogonadism, amenorrhea, and low estrogen activity in women, and, in men, impotency, decreased libido, and marked testicular atrophy.

Dietary Study on the Aged Shows Need for Research

A controlled, detailed, longitudinal study between 1948 and 1954 on the nutritional status of 577 aging persons in San Mateo County, Calif., revealed that dietary factors show a high correlation with some diseases.

The study, based on analysis of food intake and blood chemistry, was reported by Harold Choep, M.D., Dr.P.H., director, San Mateo County Department of Public Health and Welfare, and Lester Breslow, M.D., M.P.H., chief, bureau of chronic diseases, California State Department of Public Health, San Francisco.

Of 88 deaths—63 male and 25 female—occurring among the 577 subjects, 85 percent resulted from 3 causes: heart and circulatory diseases, nervous system diseases, and malignant neoplasms, they reported.

Although this series is small, it confirms other previous study findings. These are:

Heart and circulatory disease is the greatest killer of all the diseases.

The death rate from heart and circulatory diseases is 5 times greater in those over 70 than in those 50 to 69 years of age.

The death rate from nervous system diseases is about equal in men and women, but $2\frac{1}{2}$ times greater in those over 70 than in those 50 to 69.

To date the death rate from malignant neoplasms among the subjects studied is 3 times higher in males than in females, but about equal for the two age groups.

The death rate from disease of the respiratory system is 3 times higher in males than in females and 7 times higher in those over 70 than in those 50 to 69 years of age.

Dietary Relationships to Deaths

The percentage of deaths in patients with recorded systolic pressures of 180 mm. of mercury and more was 4 times higher than for those whose systolic pressure was under 140, they said. In males the percentage of deaths was $4\frac{1}{2}$ times

greater and in women only $1\frac{1}{2}$ times greater than in those with systolic pressures under 140. Diastolic pressures did not correlate to the same degree, although the death rates were slightly higher when pressure was 100 than it was when under 90.

Overweight persons were shown to have a death rate from cardiovascular-renal disease nearly double that of normal weight individuals, they said. A relationship between high cholesterol and hypertension or cardiovascular-renal deaths could not be supported by the data. Subjects with lower blood cholesterol suffered the highest death rates from these diseases, they reported.

The death rates in persons with low blood concentrations of vitamin A, niacin, and ascorbic acid was higher than in those with normal or high concentration, they said.

No significant relationship could be found between death and hemoglobin, blood glucose, blood creatinine, caloric intake, protein intake, fat intake, carbohydrate intake, calcium or iron intake, they declared.

The maintenance of a sufficient ascorbic acid intake is apparently essential for good oral hygiene to preserve teeth and prevent gingivitis, they asserted. Study subjects with ascorbi serum less than 50 mg. were 50 percent endentulous; those with 50–109 mg. were 40 percent endentulous, and those with 110 mg. were only 32.3 percent endentulous.

The Bureau of Human Nutrition and Home Economics, United States Department of Agriculture, the Public Health Service, the University of California department of home economics, the California State Department of Health, the San Mateo County Department of Public Health and Welfare, and the San Mateo County Medical Society participated in the study.

Criteria for selection of the subjects were: not on a special diet; not under the care of a physician within the past 3 months; physically and mentally capable of participating, and subjectively in good health; an equal sample of males and fe-

On the committee were representatives from the Oregon State Medical Society, State Department of Education, State Board of Health, Tuberculosis and Health Association, Cancer Society, Mental Health Association. Medical schools, the State university and college, teacher and private colleges and universities also were represented.

The policy committee developed a report on functions and competencies to serve as the basis for curriculum construction, Anderson reported. A central committee of 17, representing school administrators and teachers, developed the curriculums, as amended later by the policy committee. These were designed for preparing secondary and elementary school teachers in health.

The contents for the curriculums of colleges, secondary and primary schools were developed by 56 educators. In a 2-week workshop held at Oregon State College, the educators were assigned to subject matter committees of their own choosing. Their recommendations, edited by a subcommittee, were placed into a composite report and approved with modifications by the central and policy committees.

The final product, Anderson stated, provides the basis for certification for health teaching and also serves as guide to the schools in States preparing teachers for health instruction.

Anderson felt that the development of the standards was made possible through use of "a thoroughly democratic process" in which the persons interested in school health united their efforts.

During the general sessions of the workshop, Anderson said, the participants became acutely impressed with the need for a further understanding of school health on the part of school administrators if school health programs were to be effective. The workshop participants passed a resolution urging the State department of education to incorporate school health in the professional preparation of administrators. The

proposal was accepted and a unit was incorporated into an existing course in school administration.

Preplanning Techniques Key to Success

"More than any other educational procedure, the health education workshop provides the opportunity for the participant to assume responsibility for his own learning in an environment in which tensions are reduced, where there is emphasis on individual growth, where there is time for planning, study, observation, and recreation, and where each individual's ideas and contributions are valued."

This statement by Edward B. Johns, Ed.D., professor, school health education, University of California at Los Angeles, summed up his review of the techniques in health education workshops.

Preplanning is a prerequisite technique for producing an effective workshop, he indicated. Preplanning sessions achieve team cohesiveness, determine the need for a workshop, identify the current problems of the group, decide the central theme, he said.

Johns favored the type of preplanning in which the group develops the framework for the program, including the general sessions, with a time schedule for individual conferences and group meetings. This includes handing out such information in booklet form for distribution to the participants. It also provides for the election by participants of a program-of-work committee, giving members the opportunity to share in planning their own program.

Factors to be worked out in this stage, he said, include the following: the amount of financial support; the selection of an outstanding staff, consultants, and resource persons; the production of a brochure and agreement on the amount and type of publicity; and the size of the workshop group.

The mark of real achievement by

the preplanning group is the ability to mix the proper ingredients of program structure to give the workshop form and substance and at the same time allow for flexibility with opportunities for program planning on the part of the participants, he continued.

Mindful that some workshops have been unsuccessful because of the failure of those concerned to determine the demands of prospective members in the field, he remarked, "A workshop is not a workshop if it is a series of sessions forced upon a professional group."

One of the best means of assuring financial support is to encourage participation of the influential representatives of organizations and agencies in the preplanning sessions, he said. Other effective techniques he recommended are the following:

For the proper orientation of leaders, distribute mimeographed materials on the role of the consultant, the resource person, the chairman, and the records, plus a thumbnail sketch of each leader's function.

For evaluation of workshop results, have staff members discuss each participant's accomplishments in a staff and consultants' meeting to make sure that the progress achieved was accurately and fairly appraised.

For securing as many administrator-participants as desired, capitalize on the general interest of the administrator in healthier, happier children, youth and adults, or pay his expenses, or lure him to an outdoor workshop held in an exceptionally fine recreation area.

Pennsylvania's Workshops Show Positive Results

The workshop, a comparatively recent venture in the field of health education, among other results is proving an effective means of community-school cooperation, concluded Arthur L. Harnett, Jr., Ed.D., in charge of health education, Pennsylvania State University, in

dents, the agencies and individuals, the local communities within the State, and the States where the migrants traveled.

In each community, it was emphasized that each part of any program would be undertaken only if it was mutually agreeable to the community and the project administration.

The programs in the two camps were similar, although some policies differed. For example, in Fort Lupton, home visiting by nurses was not emphasized; in Palisade, nurses routinely called on all new families.

A medical social worker assisted in community organization and project planning and promoted inter-agency cooperation by keeping local, State, and Federal agencies informed about the project. She also gave technical consultation to the staff of both camps and direct advice to some patients, and she participated in the home followup of some of the 28 pupils in a 6-week school for children of migrants.

Problems of chronic disease and disability, among them cases of tuberculosis, were found in both camps. Although the tuberculosis patients could not meet the residence requirements for hospitalization at State expense, a voluntary institution accepted them without charge. Hospitalization of the patient often depended upon making satisfactory provision for the other members of the family, particularly the children, Howard and Perkins said.

They reported that, in both camps, the clinical conditions most frequently seen were diarrhea and upper respiratory infections. There were 35 known pregnancies in Fort Lupton, 23 in Palisade; 1 infant death and 1 delivery in Fort Lupton, none in Palisade. A puzzling finding was the incidence of burns, high in Palisade and low in Fort Lupton. Clinic services were used at some time by 22 percent of the individuals at Fort Lupton and by 17 percent of those at Palisade, they said. A summary of the use of health services in the two camps is shown in the tabulation.

	Fort Lupton	Palisade
In camp:		
Families.....	425	328
Individuals.....	2, 213	1, 316
Adults.....	1, 190	832
Children.....	1, 023	484
Seen in clinic:		
Families.....	198	135
Individuals.....	496	224
Adults.....	226	88
Children.....	270	136
Individuals seen by:		
Physician.....	319	72
Nurse alone.....	181	224
Total visits:		
Clinic.....	1, 056	385
Home (public health nurse).....	73	633

Although the experience in these two camps does not furnish an accurate picture of the medical needs of migrant agricultural workers, it can serve as a basis of comparison with future results and with the experience of other medical care projects.

Project to Continue

At the end of the season, Howard and Perkins reported, the consensus was that the project had been definitely successful and that health needs had been taken care of earlier and more smoothly than in past years. Improvement in relationships and communications between agencies was noted as each agency learned about the other's functions and resources. The work of the nursing staff with representatives of

the peach growers and in the community had resulted in better understanding of the local health department.

The program is to be repeated next year, they said. In the meantime, efforts are being made to improve communications within the communities and to overhaul and improve record forms, in consultation with interested groups, with particular emphasis on means of referral between health services. "We . . . will continue to advocate the formation of a State committee for Colorado," they concluded. "With such a committee and with the State structure properly integrated with that of the region, we believe that health services in local areas can be so developed and fitted together that migrants like other citizens can receive the care they need."

Health Education Workshop . . .

Health Training Standards Set by Oregon Workshop

Standards for teacher preparation in school health work have been established in Oregon following extensive study by professional groups.

C. L. Anderson, Dr.P.H., professor of hygiene and health education,

Oregon State College, Corvallis, reported that a professional policy committee of 17 members was formed to suggest and establish standards after the Oregon State Department of Education reported 3 years ago that the State's school health program was handicapped by teachers inadequately prepared in health.

rated on school health by the State department of education.

Accomplishments of the Program

Reviewing the accomplishments of the school health program since 1947, Farris stated that Arkansas now has part-time health coordinators in most public schools; five publications dealing with school health have been supplied to schools without charge; a section for school health coordination has been established in the program of the Arkansas Education Association; and additional personnel have been employed or personnel have been reas-

signed in the State department of health and education.

The program has pointed the way for other interested groups to improve their areas of education, Farris said in conclusion, and "we are seeing a new awakening on the part of the local school administrators." The State school superintendents and the county school administrators have formally endorsed the efforts which have been made to improve the health of school children, and both State and county schools now have an advisory committee which quite actively assists the joint coordinating committee in many facets of its program.

the Benelux countries, and over the channel into England. He has to weigh the necessity for strict quarantine of hunting dogs which, if they are shipped to the United States, could carry infected fleas from the European rabbit to the American rabbit.

The military veterinarian indirectly bolsters the economy of the host nation as he tries to solve the problem of supplying meat and milk, Juni said. He has a record of establishing new food processing industries, improving existing distribution channels, and modifying inspection methods to meet the strange new threats to health. His military food sources are cited as models by related industries in the country.

Difficulties encountered in establishing a new source of milk supply in France, for example, illustrate the necessity for compromise with the local scheme of living. A vast amount of farm sanitation had to be done at the start, making it necessary to use a separate processing operation for milk from farms meeting minimum standards. Tuberculin testing and quality control of raw milk were instituted to enable other farms to qualify for the segregated farm supply.

These obstacles were superseded by the problems of locating a water supply uncontaminated by sewage, adapting local methods of counting bacteria to American specifications, and getting the release of health certificates on dairy workers when local custom decreed that they be seen only by a licensed physician.

Tuberculosis

Potential hospitalization of infected personnel with a long-term disease such as tuberculosis means a loss to the command, Juni continued.

Tuberculosis is common in dairy cattle in Europe. Generalized infections are routinely found in local abattoirs. In some areas cattle herds are 90 percent infected, raising the question of bovine sources for extrapulmonary cases in humans. Pulmonary infections of bovine origin have been reported also in areas

Military Public Health . . .

Overseas Tasks Challenge To Military Veterinarian

Reviewing veterinary public health problems encountered at overseas military bases, Maj. Robert P. Juni, V.M.D., M.P.H., said that the military veterinarian's responsibilities range beyond food inspection activities into preventive medicine.

Formerly veterinarian with the 4th Epidemiological Flight attached to Surgeon, USAF in Europe, Major Juni is now command veterinarian, Air Proving Ground, the Eglin Air Force Base, Fla. He said that military public health in Europe embraces military families in a dozen different countries.

He ascribed the expansion of veterinary medicine overseas partly to the shortage of base-assigned physicians and sanitary engineers, and partly to the increased emphasis on the study of how diseases were actually being spread. Much of the expansion he attributed to the practical necessity for organizing workable systems.

Local foodstuffs supplied to overseas bases are entirely under the military veterinary inspection system. Procurement is complicated by local production methods, processing machinery, difficulties with languages, customs, and laws.

Military Public Health

The staff veterinarian, in peacetime Europe, improvises practical measures and initiates his public health reforms with limited personnel and limited facilities. In these circumstances, Juni said, he quickly becomes a student of the natural history of the local infective agents as well as an amateur anthropologist. Even some of the infections prevalent in the United States may have a different clinical course locally. The veterinarian steps into the role of liaison officer in his efforts to cooperate with the agricultural animal disease programs in each country.

To prevent transmission of exotic animal diseases across the Atlantic, he may find himself following the host country's epidemiological reports on myxomatosis, the well-publicized rabbit plague which spread from France into Germany,

his discussion of the 10 years of experience with workshops in Pennsylvania.

He cited the following as other results of workshop projects: They provide a method of unifying and strengthening the efforts of individuals, which otherwise might be ineffective; they give many specialists—in medicine, dentistry, nutrition, psychology, public health, and education—a chance to share in planning programs in health education; and they are a means of discovering current trends and problems in health education.

Harnett said the workshop is characterized by a program based on interests, problems, and needs of experienced health teachers or leaders; democratic procedures; ease of communication; and a variety of methods for individual and small group participation. Its social climate sheds a "halo effect" upon all the work undertaken.

Harnett reported that in Pennsylvania each of the 6 annual workshops is planned by each workshop director with the help of a central statewide committee—the Inter-Agency Planning Committee. The latter group is comprised of representatives from State departments of health, welfare, and public instructions, the State medical society, and the Pennsylvania Tuberculosis and Health Society.

Participants are selected locally, Harnett said, with guidance from the county superintendent of schools. Scholarships from local voluntary health agencies—cancer societies, heart associations, tuberculosis societies, and chapters of the National Foundation for Infantile Paralysis—are awarded to participants.

The participants later have a chance to evaluate the workshop through their own efforts. Harnett listed six evaluation procedures by which the effectiveness of the program can be judged.

1. A comparison of preworkshop questions and problems with end-of-workshop findings as to how these same questions and problems were answered.

2. A measure of health information, both factual and applied, gained by each participant during the 3-week workshop, as shown by standardized tests.

3. Evaluative statements, checks, and opinions of participants on the conduct and outcome of the workshop, particularly in relation to the effectiveness of group interaction.

4. The judgment of a representative steering committee, which meets regularly and interprets the opinions of the workshop members, conditioned by an evaluation of present program and immediate needs.

5. Periodic summaries during the workshop, such as end-of-the-week reviews, to determine changes, emphasis, and direction of the workshop program.

6. A followup questionnaire, some 8 months to a year after the workshop, to discover progress in attaining more remote or long-term objectives. Some workshops have had reunions or evaluation meetings to discuss strengths, weaknesses, and values in the workshop program.

Cooperation Features Arkansas Planning

The health of the child is of first importance in Arkansas schools, asserted Jeff Farris, M.S., director of health and physical education, Arkansas State Teachers College, Conway, and consultant in school health, Arkansas State Board of Health, Little Rock.

Farris reported that progress during recent years in developing and improving Arkansas school health programs was due to cooperative planning among State agencies.

The guiding principle of cooperative planning was to include almost every State group which had a contribution to make in planning the school health program, Farris stated. The State department of education and the State board of health have been the leaders, but the Parent-Teacher Association, the Arkansas Education Association, the Univer-

sity of Arkansas Medical Center, the crippled children's division of the State department of public welfare, the Lions Club and other civic groups, the county health departments, and most State and voluntary agencies have participated in planning and operating school health activities, he said.

Cooperative planning in Arkansas had its beginning in 1947 at the Southern States Work Conference in Daytona Beach, Fla., Farris said. While attending the conference, representatives from Arkansas decided to establish pilot programs of school health in three of the school health systems. In the summer of 1948, a workshop included a group of school superintendents who wanted their schools to be part of the pilot group. A 2-week workshop has been held every summer since then for representatives of all agencies taking part in the program. About 1,000 persons have attended these workshops, he reported.

Coordinating Activities

Perhaps the most important single administrative result of the workshops has been the Joint Coordinating Committee for Promoting Health Education in Schools, Farris said. This is a permanent group made up of an equal number of members from the State departments of health and education and is the coordinating and activating agency for all groups participating in the school health program. The chairman and the secretary are chosen from one department one year and from the other department the next. Subcommittees are responsible for the various areas of school health.

Arkansas has no special school health agencies, Farris stated, and financial, educational, professional, and civic agencies work together. One agency supplies money and others supply personnel, transportation, or materials.

The State board of education has adopted standards for school health produced at the 1951 summer workshop, Farris said. Schools are now

Milk Sanitation Honor Roll for 1954-55

Fifty-six communities have been added to the Public Health Service milk sanitation "honor roll" and 52 communities on the previous list have been dropped. This revision covers the period from January 1, 1954, to December 31, 1955, and includes a total of 270 cities and 55 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the Milk Ordinance and Code Recommended by the United States Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk is sold.

The recommended milk ordinance, on which the milk sanitation ratings

This compilation is from the Division of Sanitary Engineering Services of the Bureau of State Services, Public Health Service. The previous listing, with a summary of rules under which a community is included, was published in Public Health Reports, September 1955, pp. 910-913. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

are based, is now in effect through voluntary adoption in 422 counties and 1,600 municipalities. The ordinance also serves as the basis for the regulations of 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated

in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

Communities awarded milk sanitation ratings of 90 percent or more, 1954-55

of high incidence in cattle. Germany reports the incidence of tuberculosis as being 21.95 per 10,000 persons in 1953, with surveys indicating that 10 percent of these cases are of bovine origin.

Denmark and the Netherlands already have an eradication plan in effect. England is in the process of establishing additional accredited areas. Germany and France have the nucleus of area plans in regions in which the quartermaster corps has sponsored a milkshed.

However, tuberculosis control has been hampered by incomplete epidemiology of the disease among military personnel. Fortunately, the natural fastidiousness of the typical American plus local controls over large off-base restaurants and military inspection of local food supplies decreased the risk of infection for troops.

Other Diseases

Pets owned by military personnel have, at times, been responsible for many veterinary control problems, Juni indicated.

To control outbreaks of psittacosis, registration of parakeets and other psittacine birds is required.

Routine immunizations of household pets quickly eliminated the threat of rabies when it became known that wildlife rabies was prevalent in West Germany for the first time since the Napoleonic wars.

In Rheinland-Pfalz, when 50 percent of 179 herds of sheep tested positive for brucellosis (Malta fever), possible spread to the families of military personnel was avoided by arranging to have local veterinary police ordinances rigidly enforced before sheep were allowed to graze on military bases.

Immediate control measures were initiated when it was found that 40 percent of Air Force guard dogs in Europe and North Africa had a significant titer for leptospirosis.

The bases in the areas where leptospirosis of any type was endemic were advised of the hazard of epidemics. The protean nature of the clinical symptoms was stressed, and

arrangements were made for the submission of serum samples for definitive diagnosis. The factors affecting the size of the wildlife reservoir were watched so that epizootics and consequent epidemics could be anticipated.

The ecology of other zoonoses was studied in an attempt to evaluate other potential health hazards. One objective was the avoidance of possible breakthrough of any animal diseases. A second objective in such studies was the provision of readily accessible information upon which to base control measures in the event of outbreak, Juni concluded.

Describes Public Health In Military Government

American military experience with Civil Affairs and Military Government (CAMG) since 1940, with an outline of problems and policies, was described by Colonel James P. Pappas of the Preventive Medicine Division, Office of the Surgeon General, Department of the Army.

CAMG activities relate to the commander's responsibilities in civil-military relationships. These range across a broad spectrum with civil affairs at one end involving relationships and agreements in friendly or allied territory to "full-blown" military government of enemy occupied territory at the other end with full executive, legislative, and judicial authority, within principles of international law. CAMG was identified as an "instrument of national policy," he said.

During the combat phase, military necessity (factors relating to winning the war) and compliance with the principles of international law (Geneva Convention) require the fullest possible support by CAMG and its public health staff. Of necessity during this phase, the operational responsibility for CAMG public health falls upon the surgeon who controls medical personnel, supplies, and transportation, he explained. Further, during this phase,

military operations control is along tactical lines unrelated to political and governmental territorial organization and channels.

In the postcombat, or static, phase, the role of CAMG and tactical forces are reversed. CAMG becomes the main force to win the peace, with the occupational forces acting for security and in support, he said.

Pappas favors the early civilianization of the CAMG organization, and, indeed, the policy of the Army is to have a civilian agency of the Government assume this function as soon as possible after cessation of hostilities. The military government responsibility was not completely transferred to a civilian agency of the Government until almost 5 years after cessation of hostilities.

In a summation of the management of public health by military authorities occupying Germany, he commented that the public health services had been more or less improvised in Sicily and Italy but had benefited from considerable planning in northwest Europe. Even so, there were but a dozen physicians with about the same number of paramedical personnel available for combat-support field public health work.

Following a review of the problems and principles of CAMG public health operations in Japan and Korea, Pappas pointed out that the Korean conflict stimulated organization and coordination among all Government agencies and the Joint Chiefs of Staff designated the Chief of Staff, United States Army, as executive agent for CAMG for advice, planning, and coordination.

CAMG public health involves all the skills and techniques and problems of a national ministry of health and provincial and city health departments—only it is much more complicated and frustrating. It is surprising to some, though truistic enough in itself, that military government is government nevertheless with the ordinary problems and perplexities increased enormously.

Milk Sanitation Honor Roll for 1954-55

Fifty-six communities have been added to the Public Health Service milk sanitation "honor roll" and 52 communities on the previous list have been dropped. This revision covers the period from January 1, 1954, to December 31, 1955, and includes a total of 270 cities and 55 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the Milk Ordinance and Code Recommended by the United States Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk is sold.

The recommended milk ordinance, on which the milk sanitation ratings

This compilation is from the Division of Sanitary Engineering Services of the Bureau of State Services, Public Health Service. The previous listing, with a summary of rules under which a community is included, was published in Public Health Reports, September 1955, pp. 910-913. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

are based, is now in effect through voluntary adoption in 422 counties and 1,600 municipalities. The ordinance also serves as the basis for the regulations of 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated

in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

Communities awarded milk sanitation ratings of 90 percent or more, 1954-55

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90-percent or more com-

pliance with the grade A raw milk requirements, of the Milk Ordinance and Code Recommended by the United States Public Health Service. Note particularly the percentage of the milk pasteurized in the various

communities listed. This percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized, either commercially or at home, before it is consumed.

International Symposium on Venereal Diseases

The First International Symposium on Venereal Diseases and the Treponematoses will be held at the Statler Hotel, Washington, D. C., May 28-June 1, 1956. The symposium is sponsored by the Public Health Service and the World Health Organization.

This meeting will afford an opportunity for authorities from many lands to exchange ideas and information on developments in research, diagnosis, treatment, and case finding in the venereal and treponemal diseases. The working languages of the symposium will be French, Spanish, and English. Papers will be interpreted in all three languages during the course of the meeting.

ULTRAVIOLET STERILIZATION

in Microbiological Laboratories

A discussion of the germicidal protection offered by ultraviolet lamps installed in airlocks, at doorways, and on ceilings of microbiological laboratories and walk-in incubators.

By ARNOLD G. WEDUM, M.D., EVERETT HANEL, Jr., B.S., and G. BRIGGS PHILLIPS, B.S.

ULTRAVIOLET radiation has been used for a number of years in some infectious disease laboratories to provide barriers between hazardous and safe areas and to reduce bacterial contamination.

The decision, by the authors, to recommend installation of ultraviolet lamps in airlocks, in doorways, and on ceilings of selected laboratories and walk-in incubators was made after experiments showed that ultraviolet radiation could be used to separate areas of unequal infectious risk.

Earlier reports dealt with ultraviolet radiation for sterilizing small volumes of bacterially contaminated air and for treating single sheets of paper passed from infectious areas (1, 2).

Dr. Wedum is safety director, Fort Detrick, Army Chemical Corps, Frederick, Md. Mr. Hanel is chief of the Agent Control Branch, Safety Division, Fort Detrick, and Mr. Phillips is a bacteriologist with the Safety Division. This report is one in a series.

Wedum (3) also mentioned the use of ultraviolet racks for cages housing infected animals.

Experimental Methods

Cultures of *Serratia indica* were used in most of our studies. In some tests, normal bacterial flora of the air or surface contaminants were used as indicators of germicidal effectiveness. Aerosols of *S. indica* were produced from 24-hour broth cultures by a DeVilbiss No. 40 nebulizer.

To evaluate the effectiveness of ultraviolet (UV) installations, air was sampled for bacterial content by sieve air samplers (4) with the UV lamps off and on. In some instances liquid impinger samplers were used for the UV-off air samples. The comparative number of organisms recovered and the percent reduction allowed an estimation of the effectiveness of the germicidal radiation.

During these studies some attention was given to the phenomenon of photoreactivation, first described by Kelner (5). Recovery plates

were sometimes prepared in duplicate and incubated under white light and in the dark. However, our experiments called for lethal concentrations of ultraviolet radiation and were performed during the day when generous amounts of white light were present before and during the tests, and no photoreactivation was demonstrated. The average relative humidity in the laboratories during these studies was 56 percent.

Airlocks

In this paper an airlock is defined as a small empty room with a door at each end, constructed to create a dead airspace for a safer passage-way between two areas. Germicidal lamps were installed on the ceiling of a variety of

such rooms and experiments were conducted to determine the effectiveness of ultraviolet radiation in preventing the passage of airborne micro-organisms from area to area.

Tests conducted with one typical airlock illustrate the effect of germicidal radiant energy. Three 30-watt UV lamps were installed on the ceiling in an airlock 8 feet long, 3½ feet wide and 10 feet high. Movement of air between the rooms separated by this airlock was controlled during testing by means of exhaust fans, although in practice the room of greater infectious hazard is kept at a negative pressure.

A meter employing a WL-775 Tantalum photocell and calibrated for response at wavelength 2537A was used to determine the radiant intensities of energy throughout the airlock. All measurements were taken on a horizontal

¹ Leakage around door.

² Estimated.

NOTE: No *S. indica* appeared in control air samples taken before each test. Organisms passing through the airlock were collected with sieve samplers for 5 minutes at 1 cfm. Liquid impingers were used to determine the number of organisms per cubic foot of air at the point of nebulization. The collection efficiency of the samplers is estimated at 95 percent for the liquid impinger and 45 to 70 percent for the sieve sampler.

Ultraviolet lamp installation at doorway.

plane, and the radiation measured represented energy received from above. With the exception of one reading, all areas received at least 30 microwatts per sq. cm. (table 1).

Bacteriological tests were conducted with the doors open and closed. Aerosols of *S. indica* were produced outside the airlock on the upwind side, and samples were taken outside the airlock on the downwind side. The bacterial aerosol concentration was controlled by nebulizing a culture that had been diluted to the desired concentration. Generation of the aerosol continued throughout each test. The results show at least a 99-percent reduction of the bacterial aerosol in every case (table 2). Our experience with a variety of similarly radiated airlocks has shown that few, if any, airborne vegetative bacteria or bacteriophage particles will penetrate such a barrier if air velocities of about 2 feet per second are involved and if the number of UV lamps attached to the ceiling provide a floor intensity of 20 to 30 microwatts per sq. cm.

Doorway Barriers

In the absence of an airlock, an effective barrier can be made by providing a radiation screen across a doorway. A design we recommend for this purpose uses five 17-watt cold cathode UV lamps with aluminum reflectors placed in a wood or metal channel built around the door-

way (see drawing). The channel is placed so that the door opens away from the barrier. In this manner a screen of high intensity ultraviolet radiation is projected across the doorway.

Typical ultraviolet intensities obtained with a door barrier are shown in table 3. Intensity measurements in microwatts per square centimeter from three directions have been added and arbitrarily designated as the "total energy flux."

For bacteriological testing of the typical UV door barrier, cultures of *S. indica* were nebulized either on the upwind or downwind side of the barrier while sieve air samplers were operated on the opposite side. Two conditions were included which reversed momentarily the normal airflow pattern. For example, the pumping action of another door in the room on the positive pressure side (upwind, clean side) would pull airborne organisms from the contaminated room through the barrier door. Similarly, the opening of the barrier door momentarily destroyed the pressure balance and airborne organisms entered the positive pressure clean area.

The results of these experiments are summarized in table 4. In brief, if the total energy flux (table 3) is at least 250 microwatts per sq. cm. at the midpoint in the barrier (see drawing) the ultraviolet radiation will provide significant germicidal action.

Laboratory Ceilings

Unshielded UV lamps can be installed on the laboratory ceiling to provide germicidal treat-

Table 3. Ultraviolet intensities in microwatts per square centimeter at the vertical middle of a door barrier

Feet above the floor	Radiation from above	Radiation from left	Radiation from right	Total energy flux received
6	166	142	144	452
5	96	126	126	348
4	66	113	110	289

½	28	40	30	98

were sometimes prepared in duplicate and incubated under white light and in the dark. However, our experiments called for lethal concentrations of ultraviolet radiation and were performed during the day when generous amounts of white light were present before and during the tests, and no photoreactivation was demonstrated. The average relative humidity in the laboratories during these studies was 56 percent.

Airlocks

In this paper an airlock is defined as a small empty room with a door at each end, constructed to create a dead airspace for a safer passage-way between two areas. Germicidal lamps were installed on the ceiling of a variety of

such rooms and experiments were conducted to determine the effectiveness of ultraviolet radiation in preventing the passage of airborne micro-organisms from area to area.

Tests conducted with one typical airlock illustrate the effect of germicidal radiant energy. Three 30-watt UV lamps were installed on the ceiling in an airlock 8 feet long, 3½ feet wide and 10 feet high. Movement of air between the rooms separated by this airlock was controlled during testing by means of exhaust fans, although in practice the room of greater infectious hazard is kept at a negative pressure.

A meter employing a WL-775 Tantalum photocell and calibrated for response at wavelength 2537Å was used to determine the radiant intensities of energy throughout the airlock. All measurements were taken on a horizontal

¹ Leakage around door.

² Estimated.

NOTE: No *S. indica* appeared in control air samples taken before each test. Organisms passing through the airlock were collected with sieve samplers for 5 minutes at 1 cfm. Liquid impingers were used to determine the number of organisms per cubic foot of air at the point of nebulization. The collection efficiency of the samplers is estimated at 95 percent for the liquid impinger and 45 to 70 percent for the sieve sampler.

ceived approximately 13 microwatts per sq. cm.

During the 6-day test for each condition, normal use of the incubator was continued. The bacteria and fungi recoverable from the air by sieve samplers and from the walls by moistened sterile swabs during the test periods were reduced by 83 to 100 percent as compared to the controls (table 6). Indirect UV radiation reduced the number of micro-organisms on the floor only slightly. Direct radiation caused an 86.5-percent reduction in floor bacteria on exposed surfaces, but the reduction in numbers of fungi was not determined because of overgrowth by bacteria in the control samples.

Obviously, when ultraviolet is used, the microbial population is reduced and then remains

Table 6. Reduction of organisms by continuous ultraviolet in an incubator room (30° C.)

Condition tested	Percent reduction by ultraviolet ¹

² Very little reduction.

³ Reduction not determined.

rather constant. Equilibrium conditions were maintained although normal use of the incubator continued. When indirect UV was used, all air samples were taken close to the floor where no radiation was present. Air circulation was therefore responsible for lower air counts in all parts of the incubator. Of course, no decontamination occurred on surfaces not exposed to radiation.

The reduction of fungi was about the same as for bacteria, in spite of the fact that molds are considered to be 100 to 1,000 times as resistant as bacteria (6). This parallelism suggests that the exposure times used were sufficient to kill even the hardest micro-organisms, and, in reality, the limiting factor for destruction was the ability or inability of the radiation to reach the cells.

In an additional series of tests, when 4 ml. of an *S. indica* culture (2×10^7 cells per ml.) were nebulized in the incubator, all airborne cells were eliminated in 1 minute by direct and indirect radiation and in 10 minutes by indirect radiation alone. With the UV lamps off, *S. indica* was recovered for 1 hour.

In unreported studies, in which agar plates inoculated with *Brucella abortus*, strain A-19, or *S. indica* were placed in a walk-in incubator room equipped with UV lamps, we have observed that those agar plates placed 3 feet or closer to the lamps must be shielded continuously from the radiations to prevent inhibition of colony growth. Since 2537A radiations will not penetrate ordinary glassware, colony inhibition at distances shorter than 3 feet is

ment of the air and exposed surfaces during periods when the room is unoccupied. Lamps can also be turned on in case of accidental spillage of infectious materials and just before or during pouring of sterile media. We recommend that ceiling lamps be located to provide an intensity of 5 to 10 microwatts per sq. cm. on exposed floor surfaces.

Experiments were conducted in four rooms to determine the reduction in normal airborne bacteria when two 30-watt UV lamps, attached on the ceiling of each room, were turned on for 1 hour. Doors and windows of the rooms were closed and activity held to a minimum during the experiments. Air in the room was sampled for bacterial content with sieve samplers before, during, and after the 1-hour ultraviolet treatment. Samples were taken at the tabletop level with each sampler shielded from direct radiation. The experiment was repeated three times in each laboratory; the averaged results are shown in table 5.

One hour irradiation resulted in an 86-percent decrease in normal airborne bacteria. Common spore-forming bacteria were predominant in the UV-on samples. The number of airborne bacteria increased shortly after the lamps were turned off.

Walk-In Incubators

Conditions in walk-in incubators are generally favorable for the survival or growth of

contaminating micro-organisms. Since incubators usually are not ventilated, the microbial population may be quite high. When infectious cultures are incubated, escape of pathogens from broken flasks or from flasks with missing stoppers may constitute a hazard to persons entering the incubator. Breakage or spillage on a shaking machine or from a culture aeration apparatus may be especially dangerous.

Evaluation studies were made of the effectiveness of ultraviolet radiations in reducing surface and airborne microbial flora in a 9 x 8 foot walk-in incubator room with an 8-foot ceiling. Triplicate samples of air and surfaces in the room (30° C.) were taken for 6 days under three separate conditions and examined for common bacteria and fungi. The conditions were:

1. Control—no ultraviolet.

2. Indirect ultraviolet—one 17-watt cold cathode UV lamp mounted 8 inches below the ceiling in the center of the room and shielded to irradiate upwards.

3. Indirect and direct ultraviolet—condition (2) plus one 17-watt lamp mounted 12 inches below the ceiling and irradiating downward.

With indirect ultraviolet, radiation of from 8 to 35 microwatts per sq. cm. (due mostly to reflectance) was present on the upper shelves in the room, but no radiation reached the floor. When both lamps were burning, 17 to 82 microwatts per sq. cm. of radiant energy was present on the shelves, and the exposed floor area re-

Table 4. Bacteriological tests of an ultraviolet door barrier

Test conditions	Point of nebulization of <i>Serratia indica</i>	Position of sieve samplers	Cloud concentration per cubic foot of air			Percent efficiency of UV door barrier
			At nebulizing point	At collection point by sieve samplers		
				UV on	UV off

The collection efficiency of these samplers is estimated at 95 percent for the liquid impinger and 45 to 70 percent for the sieve sampler.

In New Jersey, allocation of State funds to local projects is proving successful in assisting control of chronic illness.

State Grants for Local Projects in Chronic Illness Control

By A. L. CHAPMAN, M.D., M.P.H., and DANIEL BERGSMA, M.D., M.P.H.

"The growing problem of prevention, detection, and care of chronic illness, which is of such a character as not to be exclusively medical, educational, or welfare, has reached such proportions in this State as to require the participation of the State and of the agencies administering public health, education, and welfare within the State, and it has been declared by statute to be the public policy of this State that the responsibility therefor must be shared by the State and the counties and the several municipalities and health districts and voluntary agencies and institutions within the State and the public at large."

THIS statement of public policy is taken from the Prevention of Chronic Illness Act of New Jersey. It represents another evolutionary step in the development of a chronic illness control program in this State—a program which began in 1949 when the Governor appointed a Temporary Committee on the Chronic Sick. The Prevention of Chronic Illness Act, passed in 1952, also called for the establishment of a division of chronic illness control in the State health department, the appoint-

ment of an Advisory Council on the Chronic Sick, and the selection of a Committee of Technical Advisors.

In December of 1952, the Governor called the first of a series of governor's conferences on chronic illness. This conference served to focus the attention of both professional and non-professional health leaders on the importance of the chronic illness problem and the need for concerted effort to solve it. Following this conference the decision was made to allocate State chronic illness funds to local sponsors.

State aid for locally sponsored projects was not a new concept in New Jersey. The basic laws of that State emphasize "home rule." The State health department has for several years contracted with local health departments for the provision of certain local health services. This policy, with only one important change, was simply extended to cover services for the chronically ill. The chronic illness grants-in-aid, however, are not limited to local health departments as are other grants-in-aid. Local boards of chosen freeholders, local nonprofit hospitals, and local voluntary agencies also can sponsor chronic disease grant-in-aid projects.

Contract Specifications

Contracts covering the State-local grants-in-aid are between the State health department and the local sponsor. They call for the provision of specific services in return for a grant-

presumably due to the longer wavelengths emitted by the lamps. Ultraviolet radiation is not recommended for incubators if it is critically important to preserve the genetic or nutritional characteristics of the micro-organisms in use.

Safety Measures

Skin or eye protection is not usually required for persons walking through ultraviolet barriers. Protection is required, however, for persons exposed to the radiation for longer than a few seconds. Personnel must be trained not to look at the UV lamps and not to loiter in an irradiated area. We recommend that warning signs and small blue indicator lights and switches be placed at each installation.

A regular maintenance program for lamp testing and cleaning is necessary. Lamps should be turned off and wiped with a soft cloth wet with alcohol. The frequency of cleaning will vary according to the conditions, but in any case the interval between cleaning should not be greater than 2 weeks. Of course, good training and good laboratory housekeeping is of prime importance in preventing the escape of harmful organisms from infectious disease laboratories.

Conclusion

Ultraviolet radiation can be used around doorways and in airlocks to separate areas of unequal infectious risk and to reduce the number of infectious micro-organisms and general contaminants in laboratories and in walk-in incubators.

Methodology Research Award

Nominations for the Fifth Kimble Methodology Research Award are being accepted until June 1, 1956. This award is given in recognition of scientific investigations affecting public health laboratory techniques.

For rules governing nominations and information on nomination procedures, write to Dr. Thomas S. Hosty, chairman, Nominating Committee, Kimble Award, Bureau of Laboratories, Alabama State Department of Health, Montgomery 4, Ala.

A significantly large sum of money has been allotted to a medical center to provide screening services to patients of private physicians upon request. Five outpatient alcoholism clinics have been started in local hospitals.

Other local projects being developed through the grants-in-aid program include multiphasic screening of State employees, cervical cancer screening in demonstration hospitals, and screening for hearing defects and the rehabilitation of the hard of hearing in two hospitals.

This is not a complete list of the many local chronic disease projects in which the New Jersey State Health Department is participating. However, it does serve to indicate how quickly and effectively a large number of institutions, agencies, and people can become involved in developing local services for the chronically ill through the expenditure of a relatively small amount of money.

The chronic illness activities of the State health department are not limited to the allocation of grants-in-aid. The division of chronic illness control is responsible also for coordinating all health services which are designed to assist the chronically ill, for public and professional education, and for planning a long-range coordinated control program.

Achievement of Objectives

The operation of a grant-in-aid program in no way negates the need for basic research work, the objective of which is to determine the causes of the degenerative and malignant diseases. Nor does it prevent the normal entrance of many nonsubsidized individuals, agencies, and institutions into the field of chronic illness control. The program does favor the more rapid achievement of several important public health objectives:

1. It almost automatically enlists the interest and support of many professional people in local chronic illness control activities.
2. It multiplies the resources and personnel engaged in chronic illness control.
3. It offers new opportunities for learning

how to provide local services that are better designed to find, treat, and rehabilitate the chronically ill.

4. It builds on spontaneous local interest where it exists. This tends to insure the efficient and economical administration of projects and favors their continuance when State aid is withdrawn.

5. It permits the State health department to exert leadership in the evolution of the chronic illness control program by selecting from among the many local applicants those that can contribute most effectively to the planned statewide program.

The rapid expansion of interest in New Jersey in chronic illness control is evidenced by the increasing popularity of the several governor's conferences which have been held since the original conference in 1952. Subsequent conferences have been held on diabetes, cardiovascular diseases, alcoholism, and new horizons in chronic illness control, including rehabilitation. All of these conferences have attracted large audiences and have resulted in excellent publicity. As a result, where originally there was a dearth of local applicants for the grant-in-aid funds, there now is a plethora.

The State-local chronic illness grant-in-aid mechanism in New Jersey is succeeding in increasing the number and quality of services offered locally to persons with chronic illness. Its important features are its simplicity of operation and its persuasiveness in obtaining the participation of local people in the solution of their own problems. Other State health departments might find that their chronic illness program can be accelerated by the adoption of the grant-in-aid mechanism.

Chronic disease grants-in-aid have proved to be, in part at least, an answer to a statement the Governor of New Jersey made in 1952: "Unless something is done by the way of effective prevention, there must inevitably be greater outlays for institutional care, and we must bear all the additional social costs—the costs in human suffering and in damaged family relationships."

in-aid, which may be in the form of money, personnel, or equipment.

When a grant-in-aid provides for the employment of personnel, the local sponsor recruits, hires, and supervises the personnel. This arrangement has proved to be more satisfactory than the assignment of State health department personnel to local projects because it gives the local agency a greater sense of responsibility for the project and because other employees accept the new employees as a part of their organization, subject to the same personnel policies. To insure the employment of qualified personnel, the State health department includes in the contract basic minimum qualifications for positions covered in each contract, based on State civil service standards. These qualifications must be met by employees recruited by local sponsors.

At periodic intervals the State health department checks the local program to make sure that the services contracted for are being provided.

Each contract provides for a specific termination date for State aid, after which the project must be maintained solely by the local sponsor. Gradual amortization is usually achieved. The contract may be terminated by either party 60 days after written notification has been given. It provides for quarterly payments to reimburse the local sponsor for actual expenditures, and it calls for the submission of quarterly reports to the State health department.

The contract also requires that the sponsor maintain proper records, make expenditures in accordance with budgets approved by the State health department, and accept general supervision and consultation by the State health department.

Federal grant-in-aid funds allocated to the State health department for the control of heart disease, cancer, and tuberculosis are not included in the State-local chronic illness grants-in-aid. They are allotted to local sponsors in much the same manner as State funds but under separate contracts. A single local sponsor may enter into one or more contracts with the State health department for the State-derived funds and also one or more contracts for federally derived funds.

Scope of Program

The following table shows the planned expenditures for chronic illness grant-in-aid funds during the fiscal year 1955-56. In conformance with the Prevention of Chronic Illness Act, the expenditures are broken down into five general categories:

Category	Amount	Per cent
Early detection.....	\$102,685	56
Prevention ¹	2,500	1
Public health nursing and home-maker services.....	13,300	7
Rehabilitation.....	47,160	25
Research ²	20,049	11
Total.....	185,694	100

¹ Primary prevention only.

² \$3,400 was allocated directly for research. In addition, 10 percent of the funds originally allocated for early detection and 10 percent of the funds originally allocated for rehabilitation were transferred to the research category.

To illustrate the diversity of activities and the broad geographic coverage that can be achieved by the use of State-local grants-in-aid, a few of the projects that have been or are being undertaken are mentioned.

Nine local hospitals have been assisted in developing multiple screening services for hospital personnel and all persons admitted to the hospital. Four hospitals are utilizing State aid to develop rehabilitation services. Two hospitals are engaged in evaluating screening tests related to diabetes control. Four community hospitals have made pilot studies of rheumatic fever prophylaxis.

The need for including bedside nursing among the services routinely offered by public health nurses has been recognized, and a study has been authorized to develop this type of program conversion. Seven community home-maker services are now functioning in New Jersey. One of these, organized on a county basis, is being assisted with a grant-in-aid to demonstrate the importance of a trained medical social worker in this field.

Two large projects are providing rehabilitation services in county institutions and hospital centers. For these projects, the grants-in-aid are in the form of trained personnel and labor-saving equipment.

ized sanitation program, that is, a program carried out by generalized, rather than specialized, personnel. However, both specialized programs and generalized programs have advantages and disadvantages. Which of the two is the more economical in terms of both cost and effectiveness remains to be determined.

All activities can be carried out by specialized personnel, but the data in table 3 indicate that certain activities are more often carried out by specialized personnel than others. Activities in the following areas were reported specialized by more than half the departments: plumbing, milk, pest and vector control, animal disease control, and industrial health.

Table 1. Comparison of the 1951 and 1954 groups of local health departments included in the studies

Population served	Number of departments reporting		Departments reporting in both 1951 and 1954	
	1951	1954	Number	Per-cent of 1954
Less than 100,000-----	3	3	1	33
100,000-199,999-----	13	8	3	27
200,000-499,999-----	15	10	6	60
500,000 or more-----	10	14	11	79
Total-----	41	35	21	60

¹ Dallas, Tex., St. Louis County, Mo., and Jefferson County, Ala., were reported in the 200,000-499,999 group in 1951 and in the 500,000 or more group in 1954.

Although there are certain activities that are more amenable to generalization than others, the data in table 4 suggest that there may also be budgetary reasons for generalization. When grouped according to the percentage of activities specialized, the health departments varied little in the average number of activities performed. However, the average per capita budget and the average per capita expenditure per activity were nearly twice as much for the departments having the highest degree of specialization as for those with the least degree of specialization.

It would be presumptuous to conclude from these few data that an activity performed under

Background of Report

This paper is based on an excerpt from a report of the Executive Committee of the Conference of Municipal Public Health Engineers. In addition to the material presented here, the report includes information on such items as salaries for directors of sanitation, sanitary engineers, sanitarians, and sanitary inspectors; policies on pay increases, holidays, overtime, vacations, sick leave, pensions, and reimbursement for transportation; professional background, educational level, and age distribution of professional sanitation personnel; and the number of clerical personnel in sanitation departments.

The study was initiated in 1954 by P. W. Purdom, director of the division of air pollution control and environmental sanitation, Philadelphia Department of Public Health, when he was chairman of the Conference of Municipal Public Health Engineers. The data were analyzed and compiled in report form by Walter A. Lyon, assistant chief of the environmental health section, Philadelphia Department of Public Health, and a member of the Conference of Municipal Public Health Engineers.

a generalized program costs less than the same activity under a specialized program. Nevertheless, such a conclusion would be supported to some extent by Fisher's observation that nearly one-third of a sanitarian's time is spent in travel (2). In a generalized program, the amount of travel is considerably reduced because (a) each sanitarian can cover a smaller geographic area and (b) overlapping of the same travel route by two or more sanitarians rarely occurs. To reach any valid conclusions concerning the economy of a generalized program, we would have to know more about the program coverage and the effectiveness of the activities in comparison with these facets of a specialized program.

Program Costs

Comparison of budget figures for environmental health programs in various health departments needs to be approached with caution, particularly when the departments vary widely

Environmental Health Program and Budget in Local Health Departments, 1954

DATA on the administration of environmental health services in local health departments were obtained during 1954 by means of questionnaires sent to all members of the Conference of Municipal Public Health Engineers. Of the 39 replies received from members associated with local programs, 35 provided information with sufficient detail and completeness to be used in the study.

In a similar study in 1951, data were obtained from 41 local health departments. Many of these data are used here for comparison. However, because not all the departments that reported in 1951 were included in the 1954 study, comparisons between the two studies are not entirely valid. As shown in table 1, only 21 of the 41 departments that reported in 1951 also reported in 1954. There is more overlap among the departments serving populations of 200,000 or more than there is among the smaller departments.

Generally speaking, the proportion of large health departments in both the 1951 and the 1954 samples is greater than the proportion in the total number of local health departments. For example, in 1951 local health departments serving populations of 500,000 or more represented 2.2 percent of all full-time local health departments (1). In the 1951 study, they represented 24 percent of the sample, and in the 1954 study, 47 percent.

Program Coverage

To obtain a picture of the program coverage provided by the 35 local health departments, analyses were made on the basis of 16 major

classifications, as shown in table 2. A health department was credited with an activity only if a comprehensive program was indicated. For example, animal disease control had to include more than just animal bite investigation.

Most of the departments (more than 80 percent) maintained routine inspection activities with respect to water, sewage, bathing places, food, and milk. More than half of the departments reported inspection activities in refuse disposal, meat, pest and vector control, institutions, and schools; and more than a quarter reported programs in housing, barber and beauty shops, air pollution, and industrial health. There seems to have been a significant increase in the number of departments reporting routine housing and air pollution control activities in 1954 as compared with 1951.

Some of the more recently recognized environmental health activities were being conducted by the following percentages of health departments: noise control, 24 percent; noxious weed control, 15 percent; home accident prevention, 27 percent; radiation protection, 35 percent.

In most of the program areas, fewer departments provided consultation services than routine inspection services. Exceptions to this were programs in plumbing, pest and vector control, animal disease control, air pollution control, and industrial health.

Of particular interest was the information reported on the degree of specialization in the administration of routine environmental health activities. In recent years there has been a trend in some departments toward a general-

capita sanitation program budgets. This exception was the 200,000-499,999 population group, for which the average per capita sanitation budget increased significantly between 1951 and 1954. As pointed out earlier, 6 of the 10 departments in this group reporting in 1954 also reported in 1951, and 3 of the remaining 4 reported considerably lower than average per capita sanitation budgets. Hence, most of the departments in the 200,000-499,999 group apparently received a significant increase in their sanitation program budgets during the 1951-54 period. That observation is substantiated by the fact that this group of departments was

the only one that reported a reduction in population per professional sanitation worker—from 15,300 to 14,500—between 1951 and 1954. For all departments, the population per professional sanitation worker increased from 13,300 in 1951 to 16,900 in 1954.

The 1954 average per capita sanitation program budget of 44 cents is four times the average amount (11 cents) spent by State health departments for environmental health services in 1950 (3). Environmental health divisions in local health departments absorbed, on the average, 25 percent of the total health department budget, whereas in State health departments

Table 4. Average per capita budget, average population served per professional worker, average number of activities, and average per capita cost per activity for 35 local health departments grouped according to degree of specialization, 1954

Percent of activities specialized	Number of health departments	Average per capita budget	Average population per professional worker ¹	Average number of activities	Average per capita cost per activity

in terms of population served and scope of program, as do those included in this study. Nevertheless, such data give some idea as to the amount people are willing to pay for environmental health services.

Budget data for the 35 local health departments, which served populations ranging from 18,000 to 2,000,000, are given in table 5. The average per capita sanitation program budget was 44 cents, with a range of 11 cents to 96 cents. Although the variation was rather wide, there were health departments in each population group with budgets near each end of this range. Environmental health divisions which were on the lower end of the per-capita-budget scale were also receiving a smaller portion of the health department budget. For example, environmental health divisions that reported a budget of less than 25 cents per capita received a median 18 percent of the health department budget, whereas those with a budget of 75 cents or more per capita received a median 40 percent of the health department budget.

The average per capita cost per sanitation activity was 4.8 cents. (As used here, and elsewhere in this report, "activity" refers to such program classifications as those listed in tables 1 and 2.)

For comparison with the 1954 data, the budget

data reported by 32 health departments in 1951 are also given in table 5. The average per capita health department budget was somewhat greater in 1954 than in 1951 for the larger departments. However, with the exception of one population group, there was little difference between the 1951 and the 1954 average per

Most of the recent reports on infectious hepatitis epidemics have concerned children in schools and institutions. The subjects of the epidemic in the Elgin State Hospital were adult mental patients.

Infectious Hepatitis Epidemic in a Mental Hospital

By OTTO L. BETTAG, M.D., FREDERICK PLOTKE, M.D.,
WERNER TUTEUR, M.D., and GUDRUN HERBORN, M.D.

DISCOVERY of any communicable disease in a mental hospital is cause for special concern. The inability or reluctance of many patients to verbalize their physical complaints frequently minimizes or rules out the possibility of early discovery and treatment. Then, too, overcrowded living quarters, intimate contact, and promiscuous defecation habits are conducive to the extension of communicable disease.

For a disease such as infectious hepatitis, poor personal hygiene and resultant unsanitary conditions constitute particularly formidable obstacles to the development of effective control measures. Certain segments of the patient population, by the very nature of their mental illness, are unable or unwilling to cooperate fully in control measures necessary to reduce the danger of an epidemic.

Thus, at Illinois' Elgin State Hospital for the mentally ill, about 40 miles northwest of

Chicago, such conditions contributed to the spread of infectious hepatitis cases, which occurred in unprecedented number from October 20, 1953 to March 15, 1954. Altogether there were 100 cases in the adult patient population of about 6,800 (see table).

Ninety-five of the 100 cases occurred in three overcrowded cottages on the north side of the grounds, Hirsch, Holden, and Hawley, housing regressed and untidy women patients. The remaining 5 cases occurred in 4 widely scattered cottages and wards for men, located on the opposite side of the grounds (fig. 1). Two of the men's cottages, Wilson, 1 case, and Kilbourne, 2 cases, housed deteriorated and untidy patients.

In general the epidemic did not follow a definite pattern. Explosive outbursts in the three women's wards were followed by a leisurely development of secondary cases. Among the men, 3 of the 4 wards developed no additional cases. Brodribb (1) and others have noted the appearance of cases in periodic batches, approximating monthly intervals.

The highest concentration of cases appeared at Hirsch Cottage, where the first two cases were found on October 20, 1953. From that date until February 13, 1954, there were 62 infectious hepatitis cases among the 267 severely regressed residents, an attack rate of 23 percent

Dr. Bettag is director of the Illinois Department of Public Welfare. Dr. Plotke, chief of the department's public health service, was recently appointed assistant clinical professor of preventive medicine at the Stritch School of Medicine, Loyola University. Dr. Tuteur is clinical director and Dr. Herborn is staff physician at the Elgin State Hospital in Illinois.

only 7 percent of the total health department budget was spent for environmental sanitation in 1950 (4). Although State expenditures for all health services increased by 245 percent during the period 1940 to 1950, expenditures for environmental health increased only 31 percent.

Constitutionality of Temporary Committal Of the Mentally Ill by Medical Certification

The Supreme Judicial Court of Maine in the case of *In re Opinion of the Justices*, 117 A. 2d 63 (May 18, 1955), has held that a statute may constitutionally provide for the temporary confinement (35 days) of a mentally ill person who is certified by a physician as being "likely to injure himself or others if not immediately restrained" provided that the statute also provides adequate methods by which persons so hospitalized may "institute (judicial) proceedings to test the necessity of their commitment."

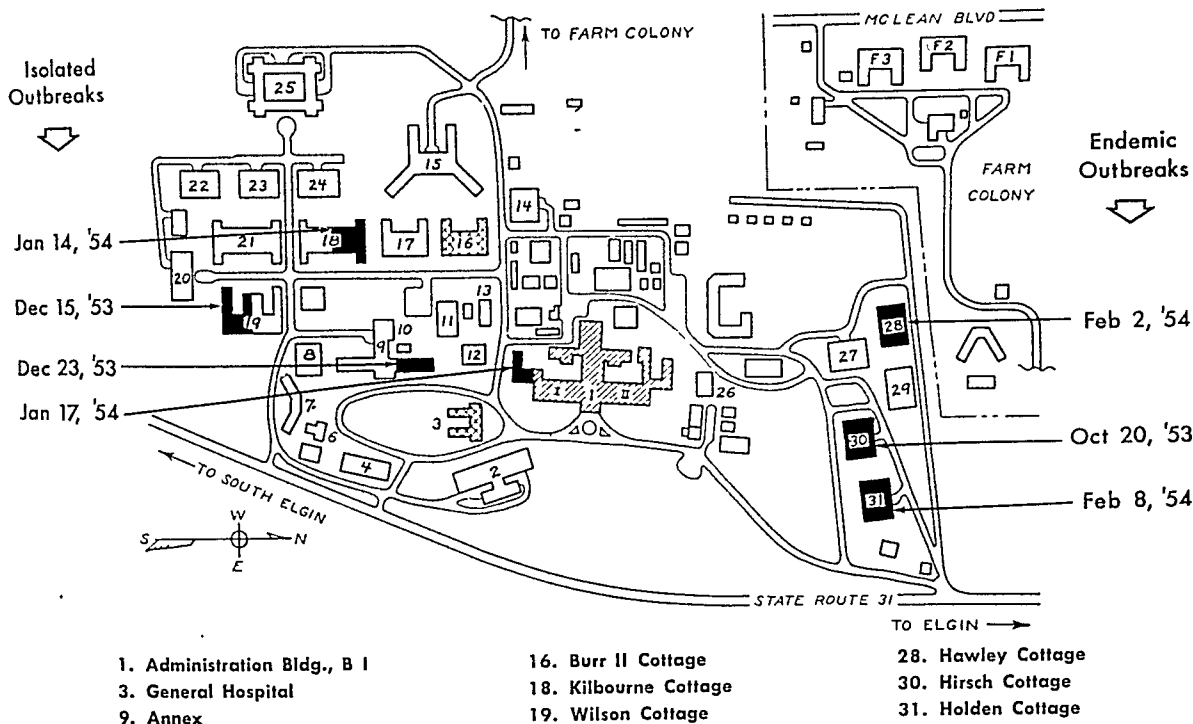

This question was presented to the court by a request for a declaratory judgment on the constitutionality of a proposed bill governing the commitment of the mentally ill. In a prior decision, *Appeal of Sleeper*, 87 A. 2d 115, this court held that where, as here, the temporary confinement is not ancillary to the institution of judicial proceedings the law requires that the person hospitalized be given an opportunity to institute judicial proceedings to test the necessity of his confinement and that this need is not satisfied by the availability of the writ of habeas corpus.

In the present case, the proposed bill adopted the language of section 17 of the Draft Act

Governing Hospitalization of the Mentally Ill (Public Health Service Publication No. 51). It provides that a patient who applies for his release shall be released within 48 hours unless the superintendent of the hospital certifies to a court of proper jurisdiction that in his opinion such release would be unsafe to the patient or others. In this case the patient may be detained for the length of time, not exceeding 5 days, necessary to institute judicial commitment proceedings.

Assuming, as this court apparently did, that the "temporary" 35-day commitment involved in this case must meet the same due process requirements as an indefinite hospitalization by medical certification, the court appears to have taken a different view than that adopted by the Supreme Court of Missouri in *Missouri ex rel. Fuller v. Mullinax*, 269 S. W. 2d 72 (Public Health Reports, October 1954, p. 982). That decision declared that such indefinite hospitalization without an opportunity for prior judicial proceedings was unconstitutional despite the presence of the remedies provided for by section 17 of the Draft Act.

Figure 1. Patient residences at Elgin State Hospital, Illinois.

sea, and diarrhea. Jaundice was observed in about one-third of the cases. All contacts, residents as well as employees in wards housing patients with infectious hepatitis, were given screening tests, including cephalin flocculation and urine urobilinogen. Residents exhibiting suspicious clinical or laboratory findings of the infection were sent to bed for observation pending confirmation of the diagnosis.

On discovery, the patients with infectious hepatitis were isolated and the affected cottages were quarantined. With the exception of the administration of gamma globulin and achromycin and special regimens for the acutely ill, the treatment and control measures were similar at the isolation units.

Preventive measures included separate garbage disposal and linen pickup. Food was served on disposable paper dishes. The basic treatment plan was relatively simple. It consisted of strict bed rest, a diet high in proteins and carbohydrates and low in fat content, a daily subcutaneous injection of 100 mg. of vitamin B₁, and intravenous injection of isotonic fluids when there were indications of dehydration.

For Hawley and Holden hepatitis patients, an isolation unit was established at Hawley Cottage. The mounting number of Hirsch patients required various arrangements for their isolation and care.

Shortly after the discovery of the first two cases at Hirsch on October 20, a special isolation unit was set up within the cottage, and the cottage was placed under modified quarantine.

Figure 2. Distribution of infectious hepatitis cases at Hirsch Cottage.

(fig. 2). The rated bed capacity is 83 patients per unit.

Holden Cottage, adjacent to Hirsch, had the second highest attack rate, 8.7 percent. From February 8 to March 15, 1954, 17 cases occurred among 194 aged, ambulatory, deteriorated women patients. The rated bed capacity of this cottage is 96 patients.

At Hawley Cottage, separated from Hirsch by cottages and grounds, 16 infectious hepatitis cases were observed from February 2 through February 20, 1954. These cases involved 6.5 percent of the 244 generally elderly and disturbed patients in the cottage. Like Hirsch the rated bed capacity is 83 patients per unit. Figure 3 shows the distribution of cases at Holden and Hawley.

Single cases occurred at Wilson Cottage December 15, 1953, and the annex, December 23. Two cases occurred at Kilbourne Cottage January 14, 1954, and one case at B I, a ward in the administration building, January 17.

No infectious hepatitis was found in any of the hospital employees or any of their family members. Approximately 1,000 employees working on a 7-day 3-shift schedule look after the welfare of the patients. The personnel live on the grounds, in the city of Elgin, or in the surrounding area. They were permitted to circulate freely on the grounds and in the town.

The employee experience at Elgin varies from that noted by Capps and associates (2) in an orphanage for children under 3 years of age. Over a period of 8 years, 72 student nurses and 3 other adults contracted infectious hepatitis from the children. Outbreaks were ultimately eliminated by emphasis on aseptic nursing techniques.

Epidemiological Investigation

Upon recognition of the epidemic an immediate, diligent investigation was made to discover the mode of transmission. The propagation of the infection by a common vehicle was considered, but so far as could be determined the water, food, and milk supplies were not contaminated. The results of all standard bacteriological tests were within the accepted normal limits. All plumbing fixtures are equipped with backflow preventers, and there was no back stoppage in

the sewage disposal systems on the involved wards. Furthermore, only 7 of the 26 cottages using the common water supply and sewage disposal system at the institution experienced an outbreak. The individual syringe technique is practiced throughout the institution in the immunization program.

Although no cases were observed among the employees, the possibility that they might harbor the virus and unwittingly spread the infection was always considered. Employee practice of proper hygiene, particularly frequent handwashing, was stressed as a precautionary measure both for themselves and their patients.

Despite investigation and followup, the exact vehicle of contamination or mode of transmission was never ascertained. While the habits and practices of the patients lend credence to the fecal-oral route, suggested by Lillienfeld and others (3) as the general mode of transmission, the relatively confined area of the spread of attack, in the absence of contradictory evidence, points to a carrier as the most likely source of origin.

Diagnosis and Management

It is generally conceded, that although mortality from infectious hepatitis is low, its protracted convalescent period and possible liver

Age and sex distribution of infectious hepatitis patients, Elgin (Ill.) State Hospital

Age (years)	Women	Men	Total
20-30-----	10	0	10
31-40-----	22	2	24
41-50-----	21	3	24
51-60-----	16	0	16

71-80-----	11	0	11
81-90-----	3	0	3
Total-----	95	5	100

damage, particularly in adults, warrants careful and extended followup and treatment in the early stages if serious after-effects are to be avoided.

The outstanding and most common clinical symptoms among the hepatitis patients were fatigue, listlessness, headaches, anorexia, nau-

oped subsequently among patients thus treated, the last one on February 13, 1954. They occurred the following dates:

<i>Date</i>	<i>Cases</i>
Dec. 15-31, 1953-----	21
Jan. 1-14, 1954-----	11
Jan. 15-31, 1954-----	4
Feb. 1-13, 1954-----	1

No gamma globulin was administered to any of the Hawley or Holden residents. But the Hawley patients with infectious hepatitis received 2 grams of achromycin daily for 5 days, while the other residents received a prophylactic dosage of 1 gram of achromycin daily for 10 days. None of the Holden residents received achromycin.

The 171 noninfected residents at the Wilson and annex units were given 5 cc. of gamma globulin. No further outbreaks were reported at either location.

Neither gamma globulin nor achromycin was administered to the residents of Kilbourne and of the affected wing of the administration building. No new cases were noted at these locations.

Psychiatric Improvements

One of the outstanding developments noted in the course of the epidemic was a marked psychiatric improvement among patients in isolation wards. Similar improvement was reported by Galioni and associates (5) in a study under comparable conditions. While on isolation status, the patients enjoyed greater personal attention than they ordinarily received in the overcrowded units.

Patients who had been in need of toilet training or had been untidy and preoccupied with their excretions prior to their transfer to the isolation units often conquered these shortcomings within 48 hours. Many who had been mute and uncommunicative and were unable to verbalize attempted to make their wishes known to attending personnel within 3 to 5 days after arrival. Many months of intensive psychotherapy would have been required to achieve a similar reaction.

This transient improvement was emphasized by the relapse of the patients into their former condition when special attention and personnel

were withdrawn on the return of the patients to their original wards.

On the other hand, no further mental deterioration was noted in the patients during or following the disease, even among the senile group, although such sequelae were reported by Noyes (6).

Summary and Conclusions

During the fall and winter of 1953-54, 100 cases of infectious hepatitis in adult mental patients were observed and treated at the Elgin (Ill.) State Hospital.

The highest incidence of cases, 98 out of 100, appeared in cottages housing the more deteriorated and untidy patients; 62 were discovered in a residence for severely regressed women possessing poor personal hygienic habits and living under grossly overcrowded conditions.

No uniform pattern of attack could be determined such as appearance of groups of cases at periodic intervals.

The lack of incidence among hospital employees caring for the patients was ascribed to high standards of personal hygiene and sanitation among the personnel.

The vehicle of contamination or mode of transmission was never ascertained, although exhaustive and continued investigation excluded, we believe, the water and food supplies and the sewage disposal system as the source. The fecal-oral route is suspected, but the area of spread also points to person-to-person contact with a carrier as a likely mode of transmission.

Marked psychiatric improvement was observed among patients transferred from overcrowded wards to isolation units or convalescent centers where they received greater individual attention and consideration. The gains were lost on return to their regular quarters.

The success reported with the use of gamma globulin in the early exposure stage during similar epidemics was not duplicated at Elgin Hospital. Thirty-seven cases developed at Hirsch Cottage during a period of 61 days following inoculation. Equivalent cessation of the secondary attack rate was experienced at Hawley and Holden where no gamma globulin was given. No spread of the disease occurred at the units housing the sporadic cases regardless

Figure 3. Distribution of infectious hepatitis cases at Hawley and Holden Cottages.

Patients were not permitted visitors from inside or outside the institution grounds, nor were they permitted to leave the cottage.

After December 1, 1953, when 10 Hirsch residents had developed the disease, all the sick patients were transferred to the institution's acute disease hospital.

By December 15, when the Hirsch cases totaled 25, the limited facilities of the acute disease hospital were severely taxed, and the infectious hepatitis cases constituted a possible hazard to the other hospitalized patients. A special isolation unit for Hirsch hepatitis patients was set up in Burr II Cottage, an infirmary for women on the south side of the grounds.

The Burr isolation ward was created by subdividing 1 of the 2 dormitories. The entire cottage, with an average of 193 patients, was quarantined.

On January 14, 1954, the Hirsch patients, 57 by this time, were returned to Hirsch Cottage, which continued under quarantine. Attending nursing personnel moved with the patients, and a special unit designated for recuperation purposes functioned until April 18, 1954.

On arrival at the Burr isolation unit, the majority of the patients exhibited mild symptoms of infectious hepatitis—diarrhea and

vomiting which stopped in a few days. Several had a moderate degree of liver enlargement.

Ten patients were seriously ill upon arrival. They developed temperatures ranging up to 104° F., severe jaundice, diarrhea, and vomiting, icterus indexes up to 10, and cephalin flocculation tests of 4-plus intensity.

Treatment of the 10 severely ill patients was supplemented by 500 mg. of aureomycin administered four times a day. Five percent glucose in saline infusions, together with vitamins B and C, were given when indicated.

Five of these patients, who exhibited low blood pressure, experienced decompensation of the cardiovascular system. They received supportive therapy in the form of digitalis, coramine, and caffeine.

One patient developed severe bilateral parotitis, in all probability caused by inadequate oral hygiene. One epileptic in this group continued to receive anticonvulsant medication in the form of dilantin-sodium and luminal, 1½ grains of each three times daily.

Three of the acutely ill Hirsch patients died. For none of these, however, did the clinical records indicate infectious hepatitis to be the primary cause of death. Three deaths were also reported from the Hawley isolation unit, 2 of patients more than 80 years old and the other 75. Here again, there was no indication in the records that infectious hepatitis was a factor in the deaths.

Gamma Globulin

Other workers (4) have reported that gamma globulin administered during infectious hepatitis epidemics has provided a high degree of protection to exposed persons.

As a preventive measure at Hirsch Cottage, 5 cc. of gamma globulin was administered to each noninfected resident on December 1, 1953. Personnel working at Hirsch (and later at the other affected cottages) were offered the same dosage on a voluntary basis, with most of them consenting to the injection.

On December 14, the remaining 242 noninfected patients at Hirsch and the employees received another 5 cc. of gamma globulin.

This attempt to control the epidemic was only moderately successful since 37 new cases devel-

oped subsequently among patients thus treated, the last one on February 13, 1954. They occurred the following dates:

Date	Cases
Dec. 15-31, 1953-----	21
Jan. 1-14, 1954-----	11
Jan. 15-31, 1954-----	4
Feb. 1-13, 1954-----	1

No gamma globulin was administered to any of the Hawley or Holden residents. But the Hawley patients with infectious hepatitis received 2 grams of achromycin daily for 5 days, while the other residents received a prophylactic dosage of 1 gram of achromycin daily for 10 days. None of the Holden residents received achromycin.

The 171 noninfected residents at the Wilson and annex units were given 5 cc. of gamma globulin. No further outbreaks were reported at either location.

Neither gamma globulin nor achromycin was administered to the residents of Kilbourne and of the affected wing of the administration building. No new cases were noted at these locations.

Psychiatric Improvements

One of the outstanding developments noted in the course of the epidemic was a marked psychiatric improvement among patients in isolation wards. Similar improvement was reported by Galioni and associates (5) in a study under comparable conditions. While on isolation status, the patients enjoyed greater personal attention than they ordinarily received in the overcrowded units.

Patients who had been in need of toilet training or had been untidy and preoccupied with their excretions prior to their transfer to the isolation units often conquered these shortcomings within 48 hours. Many who had been mute and uncommunicative and were unable to verbalize attempted to make their wishes known to attending personnel within 3 to 5 days after arrival. Many months of intensive psychotherapy would have been required to achieve a similar reaction.

This transient improvement was emphasized by the relapse of the patients into their former condition when special attention and personnel

were withdrawn on the return of the patients to their original wards.

On the other hand, no further mental deterioration was noted in the patients during or following the disease, even among the senile group, although such sequelae were reported by Noyes (6).

Summary and Conclusions

During the fall and winter of 1953-54, 100 cases of infectious hepatitis in adult mental patients were observed and treated at the Elgin (Ill.) State Hospital.

The highest incidence of cases, 98 out of 100, appeared in cottages housing the more deteriorated and untidy patients; 62 were discovered in a residence for severely regressed women possessing poor personal hygienic habits and living under grossly overcrowded conditions.

No uniform pattern of attack could be determined such as appearance of groups of cases at periodic intervals.

The lack of incidence among hospital employees caring for the patients was ascribed to high standards of personal hygiene and sanitation among the personnel.

The vehicle of contamination or mode of transmission was never ascertained, although exhaustive and continued investigation excluded, we believe, the water and food supplies and the sewage disposal system as the source. The fecal-oral route is suspected, but the area of spread also points to person-to-person contact with a carrier as a likely mode of transmission.

Marked psychiatric improvement was observed among patients transferred from overcrowded wards to isolation units or convalescent centers where they received greater individual attention and consideration. The gains were lost on return to their regular quarters.

The success reported with the use of gamma globulin in the early exposure stage during similar epidemics was not duplicated at Elgin Hospital. Thirty-seven cases developed at Hirsch Cottage during a period of 61 days following inoculation. Equivalent cessation of the secondary attack rate was experienced at Hawley and Holden where no gamma globulin was given. No spread of the disease occurred at the units housing the sporadic cases regardless

of gamma globulin administration. Possibly this agent is not as efficacious for deteriorated mental patients possessing low standards of sanitation as for other groups.

An Important Date

Each month your health department and many hospitals, laboratories, schools, clinics, and homes receive a copy of **PUBLIC HEALTH REPORTS**, mailed to arrive on the 20th, or even earlier, depending upon geographic location of the subscriber.

Its pages carry timely research reports, analyses of current trends, new methods, concepts, and ideas, and topical reviews for the busy scientist, teacher, or public health worker. Capsule coverage of important public health meetings, like those of the American Public Health Association, help the PHR reader.

You can have your personal copy promptly. Use the subscription blank on the inside back cover. Let the 20th of each month be an important date for you, too.

A Patients' Opinion Survey at Firland Sanatorium

By CATHERINE E. VAVRA, R.N., M.P.H.,
and EDITH DYER RAINBOTH

U. S. Navy photograph

WHEN Firland Sanatorium wished to find out the patients' opinions about their care and treatment so that it could make changes which would lead to greater satisfaction, it was evidence of a realization that the psychological reactions of patients affect their recovery. It also indicated the willingness of the hospital staff to see themselves through the eyes of the patient.

Some of what the staff saw pleased them very

Miss Vavra, assistant professor, department of public health and preventive medicine, University of Washington School of Medicine, was formerly director of the health education division, Tuberculosis and Health Society of Wayne County, Mich., and instructor in nursing, University of Minnesota School of Public Health.

Miss Vavra's first report on the Firland survey appeared in the American Journal of Public Health, September 1952. The present report is based on her paper for the annual meeting of the Western Branch, American Public Health Association, April 20, 1955, in Phoenix. The full report (181 pages) has recently been published and may be obtained from the Anti-Tuberculosis League of King County, Wash.

Mrs. Rainboth, co-author of the full report of this study, is assistant director of the Washington Public Opinion Laboratory, University of Washington.

much, but some of what they learned gave them insight which resulted in administrative changes in personnel, improved ways of counseling patients and assigning the nursing staff, better arrangements for good housekeeping, and specific modifications for the patients' comfort.

The Hospital Setting

Firland Sanatorium, the King County (Wash.) hospital, had moved to its present location on the north side of Seattle about 4 years before we undertook a patient opinion survey in May 1951. The new location had formerly been occupied by the Seattle Naval Hospital. After the move, the sanatorium had met the usual problems of expansion from a 400-bed unit to one of 1,300 beds, housed in 54 buildings on 160 acres of ground. Twenty-one physicians and 115 registered nurses were working full time in an administrative plant of 5 medical services, each service headed by a medical chief. The hospital was handicapped by the shortage of graduate nurses.

The medical and nursing staffs are assisted by social workers, occupational therapists, dietitians, vocational counselors, teachers, a dentist, and dental technicians. Other employees include practical nurses, nurse aides, food-service and housekeeping personnel, janitors, orderlies, and so forth, bringing the aver-

age number of employees to about 916 at the time of the survey.

Firland is fortunate in having more than adequate recreation facilities. Ambulatory patients have access to a lounge, an auditorium, a workshop, library, poolroom, music practice room, greenhouse, modern kitchen (for teaching work simplification and energy conservation), printing press, and television programs.

Movies and a patient-operated store are the most popular ways of passing time for patients having limited activity status. Mail is taken to the wards every day from a branch post office at the hospital. The large grounds and numerous pathways encourage the enjoyment of picnics and walks. A central intercommunication system and earphones or pillowphones bring the pleasure of music and entertainment programs to the bedridden. Up-patients wheel magazine carts to the patients in bed and contribute to their happiness in many ways. Many patients have their own radio or television set.

A patients' council representing the wards meets with the hospital staff to work out solutions to any grievances. Weekly broadcasts by the medical director and the reading of the hospital bulletin over the intercom help supplement the personal contacts of the professional staff and patients. Each newcomer on admission receives a pamphlet, "Welcome to Firland," explaining the rules of the hospital. Four teachers work with patients taking elementary or high school courses through an arrangement with the Seattle public schools. Religious counseling is always available, and services are held once a week or more often.

Each patient is assigned to one of the five medical services, where he usually remains from the time of admission except for temporary assignment to a surgical unit when necessary. It is hoped that this procedure gives him a feeling of continuity in his treatment and contributes to his personal relationship with his physician.

The Hospital Patients

At the time of the study (May 1951) the patient census was 1,137. The supervising nurses reported that 198 patients were ineligible for the study because they were too ill, too young, or had language difficulty, or were absent be-

cause of town leave or treatment. Of the 939 eligible patients, 91.3 percent (857 patients) completed their questionnaires.

The patient population studied (857 patients) was 60 percent male and 40 percent female. Ages ranged from 15 to 91 years. Forty percent of the men were under 40 years of age, while 75 percent of the women were in this age category. Thirty-six was the median age of all patients. Half (48.9 percent) of the women were single, widowed, divorced, or separated, but two-thirds (67.5 percent) of the men were in this category of the unmarried.

The median year of school completed by patients 25 years old and older was 11 (10.7) years, a little lower than the amount of schooling (median year 12.1) completed by Seattle residents. Twenty-seven percent had finished high school. An additional 20 percent had some college education.

Admission to Firland was the first admission to any tuberculosis hospital for 68 percent of our patients. Twenty-five percent had been here for less than 6 months, another 25 percent for 24 months or more. Eight percent had relatives who were also patients in a tuberculosis hospital. Approximately two-thirds of the patients were restricted to bed rest. Some lonely individuals (7.4 percent) never had any callers, but almost two-thirds (61.6 percent) of the patients had visitors once a week or more frequently.

Three hundred five of the participating patients were in private rooms, and the remaining 552 were in wards of approximately 66 beds each.

Need for the Study

Studies similar in purpose to our study at Firland have been made in recent years to ascertain whether patients were satisfied with the hospital care they were experiencing (1-4). Concern as to why patients leave the hospital against medical advice has led to studies of the reasons they give for not remaining until their discharge is recommended. Concern over irregular discharges was the basic reason for the Firland study.

In 1950, 44 percent (299) of all live discharges at Firland were against medical advice.

At first glance this rate appears to be high, but undoubtedly it is affected by the sanatorium's high standard of medical discharge. A patient had to demonstrate the stability of his tuberculosis over a minimum of 3 months by 7 or more hours of daily activity.

The challenge of reducing the number of irregular discharges, reactivations of the disease, and the resulting readmissions prompted the medical director and the business manager of Firland Sanatorium to initiate the patient opinion survey. By having all hospital staff members become more aware of the factors in total patient care which contribute to satisfaction and dissatisfaction, they hoped to encourage the staff to modify any practices which might hamper wholehearted cooperation with the prescribed treatment.

The purpose of this study was to obtain useful information in the operating situation. It might be described as action research in an applied setting. By obtaining patients' responses to a large number of questions, some of which were open-end, free response types of questions, we hoped to obtain information which might provide a somewhat better basis for administrative planning. No claim is made that this study is basic research of the real attitudes and beliefs of our patients. However, we feel that this type of action research did tend to point up some specific areas of satisfaction and dissatisfaction which might have some real meaning for all institutions concerned with long-term care.

Conducting the Study

The methodology of our study contains these six features which helped increase its effectiveness:

1. The cooperation of the patients' council in wording the questions, in pretesting the questionnaire for clarity and ease of administration, and in distributing and collecting responses.
2. The use of both open-end and closed-end types of questions.
3. The patients' rating of hospital personnel on 10 designated personal traits such as "interested in you," "know their jobs," "friendly," and so forth.
4. The establishment, independent of the survey, by the staff members themselves of their

own qualitative standard of performance on key questions.

5. The staff's assistance in deciding on the questions to be asked.

6. The appointment of a hospital coordinating committee to plan staff and patient participation and to help interpret the data being collected.

The coordinating committee represented each of the professional disciplines in the hospital. It included the chief of one of the medical services and a consulting psychiatrist from the University of Washington Medical School, a representative from the Washington State Division of Vocational Rehabilitation, as well as the two authors of the survey, who represented the Department of Public Health and Preventive Medicine and the Washington Public Opinion Laboratory, University of Washington. The committee met once a month.

The medical director of the hospital sent a friendly letter to all patients, explaining the purpose of the study and telling them to consider the questionnaire as an opportunity to give their opinions in confidence without signing their names.

The 857 respondents answered 105 write-in, yes-or-no, and multiple-choice questions. Altogether there were some 140,000 coded answers, which the statistical division of the Seattle-King County (Wash.) Department of Public Health helped tabulate. The patients' comments about things liked and disliked added much useful information. The content analysis of the written comments was time consuming and delayed completion of the study, but these responses gave us the best insight as to how patients really felt about their hospital experience. The analysis of the study was completed in November 1954.

Responses to the Questions

The survey attempted to elicit from every patient his opinion about almost every phase of hospital experience, including his understanding of the ways in which the staff members were working toward his recovery. Questions were asked about such items as knowledge of the disease, medical treatment, nursing service, food, routines of care, physical environ-

Firland Sanatorium Rating Worksheet for Key Questions

(Seven sample questions)

To Staff Member: The purpose of these ratings is to establish criteria by which to interpret the responses of patients to selected questions in the patients' attitude survey. For each question below, fill in your best estimate of the percentage response that you would rate as a "poor" response and the percentages you would rate as "fair," "just acceptable," "good," and "very good" responses.

Key questions	What percentage response would you rate as—				
	Poor?	Fair?	Just acceptable?	Good?	Very good?
Do you think this hospital is run with your welfare at heart? Percent answering "Yes"-----	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
Do you feel this treatment here is helping you? Percent answering "Yes"-----	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
Is there much unnecessary delay in getting a report about your X-ray and lab tests? Percent answering "Seldom or never."	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
Do you feel you are getting good care? Percent answering "Excellent or very good."	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
Are your physical complaints (like headaches, etc.) taken care of satisfactorily? Percent answering "Always or often."	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
In general, do you think you get the nursing care you need? Percent answering "Always or mostly."	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.
How often does your doctor have private talks with you? Percent answering "As often as necessary."	Less than --%	--% through --%	--% through --%	--% through --%	--% or more.

ment, patients' council, rating of traits of personnel with whom they came in contact, and special services such as occupational therapy, vocational counseling, and social service.

The patients rated high the skills and technical knowledge of the staff. They evidenced understanding of the communicable aspects of tuberculosis and of the importance of bed rest in its treatment. They admitted the inability to adjust to bed rest and indicated the extent of the inability. They revealed a lack of understanding of the functions of the medical social worker. They indicated that their chief worry was about plans for the future.

Patients tempered their criticisms of unsatisfactory experiences in the hospital with praise of other, highly satisfactory experiences. They

chose words expressing very high satisfaction or very low satisfaction when commenting about members of the hospital staff who did or did not show understanding of their problems or who did or did not treat them as individuals. Their comments and responses indicated concern about their need for more private talks with their physicians and expressed anxiety regarding delays in getting X-ray and laboratory reports.

Ninety percent rated Firland as a good hospital or one of the best tuberculosis hospitals. Only 10 percent rated their care as fair or poor. We were pleased to learn that 89 percent said that their families believed they were in the best place for care while they had tuberculosis.

Here are two examples of the closed-end ques-

tions we used and the percentage responses tabulated. In these questions, as in the other tabulations reported, the percentages mentioned are derived in each instance from the number of patients answering the questions:

Are you told ahead of time what changes there will be in your treatment?

	Percent
Always.....	35.5
Often.....	27.4
Now and then.....	18.1
Seldom.....	9.5
Never.....	9.5

Are your physical complaints (like headaches) taken care of satisfactorily?

	Percent
Always.....	51.9
Often.....	21.2
Now and then.....	18.3
Seldom.....	5.4
Never.....	3.2

Although 95 percent answering one of the closed-end questions indicated that a tuberculosis hospital was the place to go for treatment as well as to protect others from tuberculosis, only 61 percent in response to an open-end question about ways to prevent tuberculosis wrote clear-cut statements with correct answers such as: "Stay away from others, isolate the sick person." In another closed-end question indicating the degree of understanding about tuberculosis, 95 percent said it is possible to feel well and still have tuberculosis. In still another, only 86 percent recognized that tuberculosis does not always give warning in its early stages.

Comments written in by the patients covered a wide variety of topics. In the full report of the study, analysis of these comments are reported in detail (5). However some selected comments regarding the survey, the hospital, and care are as follows:

"This (meaning the survey) is the finest thing that has been done."

"If you would do more of this, we'd like it."

"This is a wonderful hospital—thanks for everything."

"The staff works out treatment in a fine way, but I believe the mental outlook of the patient is left entirely to chance."

"Good care—indifferent attitude—they feel

we are a pair of lungs in bed with absolutely no feelings whatsoever. Treatment and care conform too closely to an assembly line process."

"Care is excellent—personnel take sincere interest in my feelings and my care."

"My doctor always stops to report any news on tests and my condition and to check on how everything is going."

"I can understand that our doctors are too overworked to take time to explain, but that doesn't solve my problem of wanting to know about the progress or retrogression of my case. Wish something could be done about this."

"I know the nurses are busy, but can't we have better service at night?"

"Shortage of help makes us rush our routines until we are exhausted."

"Why can't we have our pajama tops ironed?"

"Try to get more movies—at least once a week."

Standards of Performance

Since we had no other study with which to compare the patients' reactions to their care, and yet we wished to make some kind of qualitative judgment about their responses, we asked some of the professional staff—mostly physicians, supervisory nurses, dietitians, and social workers—to experiment with us, establishing their own standards of performance in terms of patients' responses.

The staff selected 27 key questions which they thought would best reflect the patients' reactions to the care, treatment, and service the patient received from the professional and housekeeping staffs at the sanatorium. Next, the staff estimated on rating worksheets (see sample) the percentage of favorable replies which they thought would be evidence of poor, fair, just acceptable, good, or very good performance on their part. In this fashion, physicians, nurses, and some of the other members of the staff worked out estimated standards of performance for themselves as a group by a majority vote of the percentages they considered acceptable for each category.

The hospital coordinating committee selected the estimated percentage in the "good" category as the qualitative standard for each key question. Then for each key question, we compared

the actual percentage of favorable responses given by the patients with the estimated standard agreed upon by the majority of the staff as indicating "good" performance on their part. We also tabulated responses by wards so that the staff could see how their own wards performed.

"Do you know what the social worker can do for you?" a key question, is an example of how the actual responses compared with the estimated standard of good performance the social workers had set for themselves.

Percentage of patients checking "Yes," they knew what the social worker could do for them----- 48
Estimated standard of "good" performance----- 60

The social workers had estimated that a percentage response of 60 percent would indicate

a "good" standard of performance on the part of the social service staff.

Replies to the question, "Is there much unnecessary delay in getting a report from your X-ray and laboratory tests?" pointed up an area of dissatisfaction.

Percentage of patients checking "Seldom or never any unnecessary delay"----- 55
Estimated standard of "good" performance----- 75

The physicians had estimated that if 75 percent answered the question favorably, they (the physicians) would consider this evidence of "good" performance on their part. As it was, the replies showed that only 55 percent thought there was seldom or never any delay in getting reports. Only one ward met the physicians' standard in this respect, and written-in comments by the patients indicated their anxiety about delays in reports of X-ray and laboratory tests.

One of the questions which produced changes in administrative planning related to the satisfaction of having private talks with the doctors. When written-in responses to the question (table 1) were analyzed and tabulated by wards, we saw that the estimated standard was being met in only five wards. The overall responses showed that 56 percent of the patients felt they had private talks as often as necessary, but a 70-percent response had been agreed on as the estimated standard of good performance for physicians.

To Lessen Dissatisfaction

Of course, the reactions of the physicians varied. Some tended to belittle the significance of the study, saying that the criticisms didn't mean much, that the dissatisfied were probably influenced by some extenuating factor such as a neurosis or alcoholism. They called attention to the fact that 29 percent of the 299 irregular discharges in 1950 were classed as alcoholics.

Most of the physicians agreed, however, that the results of the survey reflected patient discontent in some measure and that the various criticisms should be answered by constructive changes in administrative procedures, and by serious consideration of the psychological factors which may be involved in the patients' reactions to certain administrative procedures.

Table 1. To the question, "How often does your doctor have private talks with you?" 423 patients (out of 749 answering the question) indicated by their written responses that they had private talks as often as necessary

Ward	Number of patients answering question	Respondents indicating that they had private talks as often as necessary	
		Number	Percent ¹
All wards-----	749	423	56
32-----	23	19	83
40-----	11	9	82
3-----	24	19	79
51-----	41	31	76

30-----	46	18	39
10-----	23	8	35
41-----	5	1	20

¹ Percentages are based on the number of patients answering the question in each ward.

The immediate problem was how to lessen discontent. To some it appeared that most of the areas of dissatisfaction could be eliminated by having the medical service institute a program of interviews for each patient in the doctors' conference room. The interview conference, they said, has been effective in teaching a patient about his own form of tuberculosis and about the disease in general.

The doctors proposed that the patient meet, shortly after admission and at frequent intervals thereafter, first with the chief of the service, the staff physician, resident physician, and then with the medical social worker, vocational counselor, chaplain, and any others on the staff, including nursing students, who might be able to help him understand his own case.

The patient's doctor would start the first conference by holding up the chest X-ray, explaining it in detail, pointing to the location of the disease, indicating the cavity, and so on. By encouraging inquiry about the implications of his own case, questions about the therapy—whether drugs and bed rest alone would control the disease or whether surgery might be necessary—the patient would be drawn into discussing his home problems, his future plans, his welfare. The hoped for result would be a gain in understanding for everyone.

The interview sessions have now been in effect

for 4 years. The program has been valuable in the day-to-day management of the patient. It supplies much of what each person in a tuberculosis sanatorium craves—a climate of helpfulness, a form of reassurance, and practical education about his specific form of the disease.

At present, the doctors' offices have been moved near the wards so that the doctors may have X-rays and charts close at hand and will be able to see patients every day if necessary. The change involved a reorganization in the filing arrangements and in the use of the clerical staff. It has made for a closer working relationship with the nursing staff on the wards.

Rating of Personal Traits

Our survey questionnaire gave every patient a chance to say whether he thought the doctors and others on the staff were uninterested or interested in his individual welfare. As a group, doctors, head nurses, nurses, orderlies and nurse aides, pantry maids, and ward maids and janitors were assessed by the patients in a 3-way rating of 10 personal qualities checked by each respondent. For example, for the trait "interested in you," the patient could check "often," "now and then," or "seldom" for each staff group. As with the standards of performance set for the 27 key questions, 7 of the personal

Table 2. Doctors and nurses as Firland patients saw them, percentage response, 1951 study

Quality	Doctors			Nurses		
	Often	Now and then	Seldom	Often	Now and then	Seldom
<i>Positive</i>						
Know their job.....	92	7	1	78	19	3
Try to get you to take a good cure.....	86	8	6	71	16	13
Friendly.....	83	15	2	76	20	4
Willing to listen.....	79	16	5	72	20	8
Can remember them smiling.....	78	18	4	71	23	6
Interested in you.....	75	19	6	57	30	13
<i>Negative</i>						
Crabby.....	Seldom	Now and then	Often	Seldom	Now and then	Often
Unreasonable.....	87	12	1	74	22	4
Bossy.....	85	11	4	80	17	3
Show favoritism.....	81	13	6	71	20	9
	75	15	10	68	20	12

traits were chosen for measuring good performance on the part of medical, nursing, and housekeeping personnel.

The prevailing opinion of the patients as to the personal qualities of doctors and nurses is shown in table 2 by the percentage of patients responding. For example, 92 percent of the replies indicated that these patients thought the doctors knew their job and 78 percent thought the nurses knew their job. The quality "interested in you" rated the lowest response for all personnel and rated 75 and 57 percent, respectively, for the doctors and the nurses.

During the 4 years since the study was made, there has been a gradual weeding out of the nurses, nurse aides, and others who were showing little interest in the patients. Also there has been serious discussion among the medical staff and nursing personnel regarding the importance of having the patient realize that they are "interested in him as an individual."

To assist with the educational program for patients and staff, a full-time professional health educator has been employed as of February 1956.

Some Other Improvements

Some of the changes in the hospital setting at Firland Sanatorium we attribute to the staff's seeing their own performance from the viewpoint of the patients, but there have been many other changes. Changes have been made in the administration of the nursing department, for which the orientation of all new staff members was revised. The nursing program has been adapted to the needs of different personnel on the staff. Some of the head nurses are assigned to smaller units to provide for better ward coverage, both during the day and at night.

All new employees and employees formerly assigned to night duty have an opportunity to work on the day shift. Classes in advanced procedures are held for selected groups of practical nurses assigned to evening duty, and review classes are held for practical nurses and orderlies. Additional assistant housekeepers have been employed in the housekeeping department to supervise the work of the janitors and maids. The laundry has benefited from

changes in personnel and from improved methods of handling lost articles. We now iron pajamas.

Changes made in the dietary department provide closer supervision of all foods checked out of the kitchen. Subordinate leaders are being developed from among the cooks, pantry workers, dishwashers, and counter girls. The relationship between the dietary department and the nursing and medical departments has been more clearly defined for ward personnel. On-the-job training is given to pantry girls for whom a special training manual has been developed also. Methods of keeping food hot, tasty, and attractive have been worked out and put into practice. We find we can serve coffee hot instead of lukewarm, a criticism that cropped up frequently among the questionnaire responses.

We now have movies every week.

It is not possible to recount all the changes that have resulted from the study. Some improvements no doubt would have come about because of the extensive use of chemotherapy in treating tuberculosis, reducing the average length of stay from 18 months to 8 months. Other improvements would have been expected from the staff's constant effort to lessen dissatisfaction and give the best possible care to each patient. We think we have made some progress in getting patients to feel that their physicians and nurses have a warm interest in their well-being, but such progress is hard to measure.

To whatever circumstance we attribute the changes, the discharges of patients against medical advice decreased from 44 percent of all live discharges in 1950 to 15 percent in 1954. To us this indicates that many of the factors causing dissatisfaction have been removed.

A Supplementary Study

A second study to refine our questionnaire and to ascertain the current opinion of patients about their hospital experiences was made in June 1955. In this second study we have attempted to design a questionnaire which can be used periodically, and for practical purposes it has been limited to about 65 items. As the research team worked on this second survey, two of the problems on which they have concen-

trated are (a) the problem of having staff members show more interest in their patients and (b) the need for better communication between physicians and nurses and between professional staff and patients.

During the early planning stage of the second study the five medical chiefs of service and the supervisory nurses voted to become active members of the research team rather than just members of the hospital coordinating committee. This made for an even closer relationship with the hospital staff than during the earlier survey. A staff member of the Anti-Tuberculosis League of King County, which contributed funds for publishing the first report (5), also is a member of the committee.

The results of our 1951 study have shown that Firland personnel have accepted an action study of their own behavior—a survey which involved themselves in its plan, conduct, and interpretation. Their willingness to take action on the findings, plus their ability to work together as a research team with the technical consultants, is in itself an accomplishment. The willingness to repeat the survey indicates an acceptance of

research methods to get at an understanding of dissatisfaction.

Uterine Cancer Detection Studies

Eight cities have been selected for additional evaluation studies of the exfoliative cytology technique for detecting uterine cancer: Louisville, Ky.; Madison, Wis.; Detroit, Mich.; Charlotte, N. C.; San Diego, Calif.; Providence, R. I.; Columbus, Ohio; and Washington, D. C. Preliminary evaluation of the technique was conducted in Memphis, Tenn.

The new projects will begin as soon as arrangements are completed with sponsoring or cooperating local health and medical agencies, and each will continue for about 3 years. In some localities, the National Cancer Institute of the Public Health Service, will staff and equip local clinics and agencies; in others, grants will be made to support work that will be carried out entirely under local auspices.

A report of the study in Tennessee was presented in the April 1955 issue of *Public Health Reports*, p. 341.

Sanitation of Domestic Airlines

By WILLIAM H. MEGONNELL, M.S., and HOWARD W. CHAPMAN, B.S.C.E., M.P.H.

COMMERCIAL AIRLINES of the United States have achieved a notable degree of progress in cleanliness and sanitation.

Today's air passenger is provided many more comforts than were available in earlier aircraft. Airline companies properly insist that practicable passenger conveniences unquestionably contribute to the continued success of air

transportation. However, the installation of water systems, toilets, and galley facilities, such as are found on railway cars and ocean-going vessels (1, 2), is necessarily adjusted to the primary considerations of safety of the passengers and crew and weight and space conservation in all phases of airline operation.

The domestic scheduled airlines carried more than 32 million passengers in excess of 16 billion passenger-miles during 1954 (3). There was a tenfold increase in the number of passengers carried and the passenger-miles flown in the short span between 1942 and 1954. Nineteen scheduled lines operated 186 aircraft in 1942. Twelve years later there were 32 lines with 1,175 craft. Comparable figures are not available for nonscheduled lines, but their growth probably paralleled that experienced by the regular airlines.

Public Health Significance

All parts of the world can now be reached by air within the incubation period of the major infectious diseases.

Mr. Megonnell, at present doing graduate work in public health at Harvard University, is a sanitary engineer in the Division of Sanitary Engineering Services, Public Health Service. He is co-author, with E. C. Garthe, of Dining Car Sanitation in the United States, published in the January 1955 issue of Public Health Reports (p. 25).

Mr. Chapman is co-author, also with Mr. Garthe, of Sanitation Aboard American Flag Vessels, which was published in October 1952 (p. 963), and was the first of the articles on the carrier-inspection functions of the Public Health Service. Mr. Chapman is Public Health Service regional engineer for Region IV (Atlanta).

Obviously, the rapid development of long-range air transportation is a source of much concern to public health authorities. It is the Federal Government's responsibility to institute protective measures aimed at preventing the introduction, transmission, or spread of communicable diseases from foreign countries to the United States, and in this country, from one State to another. When the Congress granted interstate quarantine authority to the Public Health Service in 1893 (4), however, only balloonists traveled by air.

The Service devoted little attention to the matter of airline sanitation until the early 1940's. In wartime, as swift transportation became vital to national survival, servicemen and defense workers took to the air in unprecedented numbers. To provide public health workers and carrier employees with necessary information and guidance in conforming to the Interstate Quarantine Regulations (5), the Service in 1942 published the Sanitation Manual for Land and Air Conveyances Operating in Interstate Traffic (6). Limited association with the airline industry up to that time and relatively long experience in railroad sanitation made it inevitable that the Service base the manual largely on land-carrier operations.

Before the war, the largest commercial airliner seated 21 passengers. The longest flight was approximately 800 miles and required about 4½ hours of flying time. After the war, the commercial airlines converted a number of military aircraft into passenger planes, designed to carry from 40 to 50 passengers on flights of several thousand miles. Subsequently, faster planes with additional passenger capacity were built.

The use of larger and faster conveyances results in two important factors of public health significance: (a) The carrying capacity creates in proportion the need for food, water, and beverage containers, wash water tanks, and toilet facilities, and (b) speed and flight range shorten the travel time between endemic disease areas and areas susceptible to infection. Airline personnel were applying to their sanitation problems the ingenuity typical of the industry, but there was little or no standardization of equipment or uniformity of operation among the carriers. The possibilities of disease transmission

That Ridiculous Pork Chop

"I had a pork chop at a height of 8 miles above the earth's surface. . . . Find yourself slipping through space in a comfortable armchair at just under 500 miles per hour, your hat in the rack above your head and the nearest point of the earth's surface some 40,000 feet below you; it is hard to think of anything that could make you more acutely sensible of your singular situation. But a pork chop does it. Sizzling hot from the galley they brought it to me, and I looked at its homely outline and then out along the steady, silver wing into the deep blue dome of the sky, and I thought of the pitiless sub-sub-zero unbreathable air in which we hung and the long, long drop below—and then I looked back at my plate again and somehow, suddenly, the whole sweep and sublimity of man's miraculous achievements seemed to be summed up and crystallized in that ridiculous chop. What business had such a thing to be 8 miles up in the air? . . . It tasted—and I remember being surprised at that, too—much as usual."

—From H. F. ELLIS, *Meals in Motion*,
The Atlantic, August 1954, pp. 93-95.

together with the growth of the air transport industry made apparent the need for a comprehensive handbook devoted exclusively to standards of interstate airline sanitation.

To meet this need, the Service published the Handbook on Sanitation of Airlines in 1952 (7). The Joint Committee on Airline Sanitation, a committee composed of caterers and representatives of the airlines associated with the Air Transport Association of America, collaborated closely with the Service in the preparation of the text. Representatives of other airlines and many State health departments reviewed the preliminary draft.

The publication sets standards on all facets of interstate airline sanitation for domestic air carriers. United States airlines operating in foreign traffic follow the same standards, whenever practicable, in their overseas operations.

The handbook is intended for the use of designers, builders, caterers, and servicing area personnel as well as operators of aircraft. Some day it may serve to stimulate the formu-

lation of comprehensive international standards since sanitation, in common with other phases of airline operation, has universal application and importance.

Airline Food Service

In their efforts to attract and hold new business, aircraft operators vie with each other to provide tasty, attractive meals for passengers. This culinary spirit is probably not so keen in the United States as it is in other countries, where planes on epicurean flights at times go out of their way to provide time aloft for the eating of meals. Nevertheless, domestic scheduled airlines today are spending more money to feed their passengers than they spent not many years ago to fly them. The cost for complimentary meal service on scheduled airlines in 1954 was more than \$22 million.

Overseas airlines are often equipped with galleys for the storage and preparation of pre-cooked frozen foods. This type of service on domestic airlines is precluded by weight, space, and flight-time restrictions.

Foods and beverages for domestic aircraft are prepared in catering establishments or carrier-owned commissaries. Airline catering has become a specialized trade. Airline equipment has been devised for the packing, storing, and transporting of meals. As a precaution against contamination of food and drink from the time the meals are prepared to the time they are served aboard the plane, lightweight and compact mechanical refrigeration units have been developed for aircraft.

Meats, cooked vegetables, and other hot comestibles are placed in casseroles, where they are kept hot either in large, preheated vacuum jugs or in portable, electrically heated ovens.

Cold portions of meals, such as salad dressing, bread, butter, dessert, cream, and condiments, along with utensils and napkins, are placed on trays which are packed in carrying cases, with dry ice.

Beverages are stored and transported in stainless steel, constant-temperature containers, which often are chilled by dry ice placed in a recessed tube in the lid of the container.

After the meal, unconsumed foods and soiled utensils are returned on the individual serving

trays to the carrying cases. Liquid and paper wastes are put in covered or enclosed metal receptacles. Tray carriers and waste containers are removed by catering personnel for emptying and cleaning, prior to re-use on later flights. Suitable refuse containers, storage areas, and container-cleaning facilities must be provided at the catering point.

It is not feasible to clean and destroy microbes on multi-use eating and drinking utensils aboard aircraft, where water supplies and waste retention facilities are restricted by space and weight allowances. Since washing is necessarily performed at ground installations, enough utensils are needed on the craft to give each passenger a clean set.

Preventing Food Contamination

There has been a strong cooperative effort directed against the contamination of food. Galley equipment is designed to facilitate cleaning by the aircraft operator in compliance with food sanitation standards. Rounded corners, tight seams, and removable parts aid in preventing accumulation of dirt and harborage of vermin. Unless design and construction are combined with proper cleaning and mainte-

Foods and beverages are delivered in enclosed carts.

nance, insects and rodents may be attracted aboard aircraft by remnants of food in the cabin and in the galley area (8).

Despite precautions, few operating airlines have escaped at least one outbreak produced by food contamination although outbreaks reported have been relatively minor, both as to number of cases and seriousness (8, 9).

Symptoms often develop within a short time after swallowing contaminated food. Unquestionably, a pilot suffering from severe nausea, vomiting, headache, diarrhea, or cramps would be strained to assure the safety of his plane, passengers, and crew. Thus, although the primary aim of sanitation is to prevent the spread of communicable disease, an immediate benefit of the program is to enhance safety by protecting the health of the pilots.

Serving of box lunches on commercial airlines has increased with the advent of tourist flights. Box lunches often are served during military movements and other chartered flights. Foods usually included in box lunches are particularly vulnerable to contamination. Aircraft have no equipment for keeping box lunches hot or cold to retard bacterial growth. The selection of food for a box lunch and its management require unusual consideration.

Two violent outbreaks which occurred simultaneously on planes of two domestic airlines in 1954 were traced to box lunches prepared by one caterer. Both outbreaks affected military personnel on charter flights.

Also in 1954, several crew members and about half of the passengers became violently ill aboard a United States plane operating in foreign traffic. Fortunately, the plane was returned safely to a stopover point. There the sick were hospitalized. Sandwiches served on this flight had been prepared at a foreign station and were found to be grossly infected with staphylococci.

Alerted by these experiences and aware of the inherent dangers to health in box lunch food service, the Joint Committee on Airline Sanitation sought the recommendations of the Service in preparing a specific sanitary guide for the safe preparation, storage, and handling of box lunches. The result was the Guide to Safe Airline Box Lunch Service, which the committee has recently issued to all airline caterers.

The prolific growth of pathogenic organisms in box lunches is generally attributable to inadequate refrigeration or lack of refrigeration. Recently, several catering chains have purchased portable, insulated, mechanically refrigerated carts in which to store lunches and transport them to the points of sale.

Aircraft Water Supply

The availability of safe, potable drinking water is no less important in the plane at 10,000 feet than it is at ground level in the cities and towns. Concern over the quality of drinking water prompted intensive activity in airline sanitation.

Bacteriologically unsatisfactory drinking water samples in alarming proportions were collected from aircraft in 1951. Extensive water sampling and bacteriological examinations revealed the condition to be widespread. Airlines, caterers, and the Public Health Service agreed that the observations pointed clearly to the need for close attention to sanitation, not only of drinking water supplies but of all aspects of airline operation.

Corrective measures were introduced without delay. Immediate action consisted of establishing continuous procedures for the detection and repair of structural flaws which develop through usage in portable water containers and for careful cleaning, filling, storage, and handling of the containers. Manufacturers were urged to improve the design of equipment to conform with sanitary construction standards.

Drinking water is usually supplied in 2-quart, 6-quart, or 8-quart stainless steel, constant-temperature containers, which are filled at catering establishments. The largest containers have recessed tubes, built integrally with the lids, into which ice can be placed for chilling the water. The apparent simplicity of this procedure belies the serious problems encountered by airlines in providing safe, palatable water.

Except in certain large planes, wash water is supplied from a separate system. This is usually of rudimentary design, consisting of a tank in, or near, the toilet room and a short length of pipe through which water flows by gravity to the draw-off point at the lavatory sink.

lation of comprehensive international standards since sanitation, in common with other phases of airline operation, has universal application and importance.

Airline Food Service

In their efforts to attract and hold new business, aircraft operators vie with each other to provide tasty, attractive meals for passengers. This culinary spirit is probably not so keen in the United States as it is in other countries, where planes on epicurean flights at times go out of their way to provide time aloft for the eating of meals. Nevertheless, domestic scheduled airlines today are spending more money to feed their passengers than they spent not many years ago to fly them. The cost for complimentary meal service on scheduled airlines in 1954 was more than \$22 million.

Overseas airlines are often equipped with galleys for the storage and preparation of pre-cooked frozen foods. This type of service on domestic airlines is precluded by weight, space, and flight-time restrictions.

Foods and beverages for domestic aircraft are prepared in catering establishments or carrier-owned commissaries. Airline catering has become a specialized trade. Airline equipment has been devised for the packing, storing, and transporting of meals. As a precaution against contamination of food and drink from the time the meals are prepared to the time they are served aboard the plane, lightweight and compact mechanical refrigeration units have been developed for aircraft.

Meats, cooked vegetables, and other hot comestibles are placed in casseroles, where they are kept hot either in large, preheated vacuum jugs or in portable, electrically heated ovens.

Cold portions of meals, such as salad dressing, bread, butter, dessert, cream, and condiments, along with utensils and napkins, are placed on trays which are packed in carrying cases, with dry ice.

Beverages are stored and transported in stainless steel, constant-temperature containers, which often are chilled by dry ice placed in a recessed tube in the lid of the container.

After the meal, unconsumed foods and soiled utensils are returned on the individual serving

trays to the carrying cases. Liquid and paper wastes are put in covered or enclosed metal receptacles. Tray carriers and waste containers are removed by catering personnel for emptying and cleaning, prior to re-use on later flights. Suitable refuse containers, storage areas, and container-cleaning facilities must be provided at the catering point.

It is not feasible to clean and destroy microbes on multi-use eating and drinking utensils aboard aircraft, where water supplies and waste retention facilities are restricted by space and weight allowances. Since washing is necessarily performed at ground installations, enough utensils are needed on the craft to give each passenger a clean set.

Preventing Food Contamination

There has been a strong cooperative effort directed against the contamination of food. Galley equipment is designed to facilitate cleaning by the aircraft operator in compliance with food sanitation standards. Rounded corners, tight seams, and removable parts aid in preventing accumulation of dirt and harborage of vermin. Unless design and construction are combined with proper cleaning and maintenance,

Foods and beverages are delivered in enclosed carts.

Design of Water Systems

Aircraft water systems in the past were designed after other equipment layout was completed. As a result, the amount of leftover space available determined the size, shape, and location of tanks, complicated their accessibility, and invited possible contamination. If the space for water tanks is allocated during the early design stages, the water system can be planned in relation to the entire plane and its intended use.

As with other engineering developments, simplicity generates dependability so that a well-designed water system is free of unnecessary, complicated parts which require maintenance and which are subject to breakdown. Simplicity makes the gravity-feed system desirable, but inflexibility of tank location sometimes makes it impracticable. Since there is usually little room in the roof of a passenger cabin to install tanks in keeping with the decor, it is often necessary to install an electric pump or other force type of feed which does not limit the tank size and location.

Sanitary design requires that the water tank have no interior cracks, open seams, or protruberances which might provide harborage for contaminants. Careful choice of materials for tanks can prevent subsequent corrosion as well as possible contamination of the water with metal salts which may be harmful to health or unpleasant to taste or smell. Equal care given to the selection of any required protective coatings will prevent possible toxic effects.

Prevention of freezing is the principal difficulty in assuring trouble-free installation of aircraft water systems. Direct contact between the fuselage skin and the water system is avoided by proper location or insulation of tanks and pipes. A completely drainable system which can be emptied easily may escape damage when the plane is standing idle in freezing weather. It is easy also to flush such a system periodically.

Sanitary design requires a distribution system protected against the introduction of contamination by backflow. A vacuum breaker should be installed in the supply line when the water delivery to fixtures is not through an air-gap.

Water drawn from any tap on the water system of an aircraft should be fit for human consumption, but it takes careful planning and good maintenance to adhere to this standard.

According to the Interstate Quarantine Regulations, water must be safe in quality and handled in a sanitary manner before it is considered acceptable for use aboard carriers. Therefore, the use of strainers or filters in aircraft water systems is not required by the Public Health Service.

When filtering devices are provided aboard aircraft, the Service recommends that they be easily accessible and so constructed that they can be cleaned and sterilized or replaced with sterilized units routinely. Otherwise, filtering devices tend to harbor bacteria. Sometimes use of the filter promotes a false sense of security to the extent that cleaning and sterilization are neglected.

Similarly, treatment of water aboard air conveyances is not required. However, a carrier's decision to practice supplemental treatment may be an added safeguard.

Along the international airways, there is interest in design of the water-servicing panel on the skin of the ship.

If the panel is opposite to the sewage and other servicing panels, there is less possibility of contaminating the water during the filling operation. This possibility is reduced still further when the water panel is clearly labeled and protected from dirt, oil, and other contaminants by a hinged cover. Connections should be quick-coupling and of a size different from other connections. They should be fitted with tight-sealing caps, with keeper chains.

As airports lack hydrants on the ramps, water is usually transported to aircraft in carts. The Service recommends that these be of sanitary design, cleaned routinely, clearly labeled, and used for no purpose which could affect the quality of the water. A direct hose connection from a hydrant to the aircraft water tank would, of course, minimize water handling and chance contamination.

Aircraft Sewage Disposal

Commercial airlines rightly insist that toilet facilities on the planes be adequate, convenient,

On older craft, the tanks are filled from buckets. The tanks on newer planes are filled by pumping water from a movable cart.

Waste water is discharged directly overboard from older aircraft. On pressurized planes, waste water generally is stored in retention tanks so as to avoid the complicated airlocks or similar devices which would be necessary to prevent pressure loss.

Indications are that the entire general system for supplying drinking water on domestic aircraft will be revised in the future.

Single Water Systems

The history of unsatisfactory bacteriological quality of drinking water in many constant-temperature containers, the extra handling involved, and the constant vigilance necessary to prevent chance contamination of the water when portable containers are used led the Public Health Service to advocate the installation on aircraft of single water systems which supply potable water for drinking, washing, and all other purposes. Single water systems are to be found on some air conveyances operating in international traffic, on some foreign aircraft, and on some planes of one domestic operator.

The many technologic problems to be considered in designing a satisfactory and sanitary water system for aircraft are complicated by space, weight, and safety considerations. In view of weight limitations, the amount of water permitted is small. However, water may be even more necessary aboard planes than it is on surface carriers because of the problem of maintaining ground temperature and humidity conditions in passenger cabins at operating heights (8, 10).

Cumberland and Bowey (10) report the experience of British Overseas Airways Corporation, which might be considered in estimating water supply requirements on United States flights. On BOAC planes, 3.75 pounds of water per passenger has been found to be adequate for drinking and washing purposes on flights of 1 to 3 hours' duration; 6.88 pounds for day flights; and 9.38 pounds for night flights of 3 to 5 hours. Ten pounds per passenger is provided on flights from 5 to 12 hours long.

Comparable information on United States

Filling an aircraft water system at stopover point.

flights is not available. However, McFarland (8) estimates that the average water intake for a passenger on an air transport is about 1.4 pounds during each 6 hours of flight. Since one-half of this amount would be available in the food served aboard the plane, it would be necessary, if food is served, to provide only 0.7 pound of drinking water per person for a 6-hour flight.

Estimates of the amount of water required for washing are more variable. On large aircraft, the supply ranges from 5.0 to 6.7 pounds a person. United States transoceanic airlines supply at least 10 pounds of drinking and washing water for each person on overseas flights of approximately 12 hours.

These seemingly small water requirements account for a significant weight increment in larger craft. The problem has stimulated research on the possibility of recovering water by various means during flight. Water recovery from engine exhaust gases, reclamation of used ablution water, and recovery of water vapor condensate within the aircraft have been investigated as possibilities. Up to now, each of these leads has proved unsatisfactory because of engineering, hygienic, esthetic, or safety implications.

ternal servicing, it was necessary to introduce valves, piping, and other fittings into the containers.

Odor Control, Incineration

Although odor-destroying substances are used in aircraft sewage retention tanks, the Public Health Service does not accept their use in lieu of effective cleaning. The product used must suppress sewage odors for prolonged periods over a wide range of temperatures, but it should not be a nuisance or a danger to the passengers or craft. It is important that it not mask odors of leaking gasoline, hydraulic fluid, oil, smoke, or other danger signals normally detected by the sense of smell.

It is required that the toilet room and galley be as distant from each other as possible. Vitiated air from toilet rooms is discharged overboard rather than recirculated in the plane's air-conditioning system. This system of ventilating is effective during flight, but not always at stopover points and terminals.

The airtight, watertight receptacle used by airsick passengers for containers should likewise be widely separated from the galley.

Current research and development appear to be concentrating on incineration of sewage and dejecta while the plane is in flight. An electric incinerator has been developed, but its power requirements may be excessive for present aircraft. Incineration by fuel or electricity is complicated by safety considerations.

Other Health Services

As with vessels and railroad passenger cars, the Public Health Service awards Certificates of Sanitary Construction for aircraft constructed in compliance with requirements of the Interstate Quarantine Regulations. Review of plans and specifications concerning features with health significance assures that defects which might require subsequent costly changes are not built into a plane. It is becoming general practice for carriers to specify that the manufacturer must obtain the certificate before delivery of a conveyance will be accepted.

To assure compliance with the Interstate Quarantine Regulations relating to the sanitation

of food, water, milk, and frozen dessert supplies, a continual program of inspection is conducted in cooperation with State health departments. Subsequent to each inspection, a source is classified as approved, provisionally approved, or prohibited for use by interstate carriers.

Airlines are kept informed of the sanitary status of suppliers by the semiannual publications, the Official Classification of Airline Catering and Watering Points and the Official Classification of Milk and Frozen Dessert Sources.

Approximately 200 servicing areas are regularly inspected. Plans for construction or major reconstruction of terminal facilities are reviewed when public health is concerned, and inspection and consultation are continued during construction.

Public Health Service and State and local health department technicians are prepared to investigate disease outbreaks occurring on aircraft.

Service personnel of the regional offices are prepared to instruct airline employees in airline sanitation, to assist in developing visual aids and other educational material, and to interpret regulations for carriers as an aid in the formulation of company rules governing airline employees.

Service studies and investigations relating to airline sanitation are conducted to assure that equipment is designed and fabricated in accordance with standards and requirements of the Interstate Quarantine Regulations.

Problems faced by United States airlines which operate overseas are particularly perplexing. Most of these lines attempt to follow the standards established for interstate travel in the Handbook on Sanitation of Airlines. They conscientiously try, by the most appropriate means, to load only acceptable food, milk, and water supplies, and to provide adequate facilities and operating procedures for the safe and sanitary disposal of sewage and refuse. Their efforts, nonetheless, are greatly complicated by local customs, illness among native workers, and public health practices which are not consistent at all stations.

Aircraft sanitation services are fitting items for international standardization. The Public

Sewage Disposal on a Modern Airliner

and inoffensive. Consequently, the design and installation of sewage facilities are now facets of the aeronautical sciences (11).

Both Interstate Quarantine Regulations and the International Sanitary Regulations (12) prohibit the discharge of excrement from aircraft in flight. None of the methods investigated for rendering sewage innocuous prior to disposal overboard have proved satisfactory from medical or engineering viewpoints (8, 11, 14). Sewage is stored aboard the plane pending disposal at servicing areas.

Present weight and space limitations preclude the provision for flushing water and storage tanks. A system employing waste wash water for toilet flushing, built into a few airplanes, was later removed because of operating difficulties.

On older aircraft a chemical toilet retains sewage wastes, and a small amount of deodorant-disinfectant solution is placed in a carry-out pail, housed in a vent chamber.

At the airport, a maintenance man carries the bucket through the passenger cabin to a cart or truck to be emptied into a sewer. The bucket is cleaned inside a closed cabinet connected to a sewer, recharged with chemical solution, and returned to the plane.

On newer planes, however, the toilet-servicing panel is recessed in the skin of the fuselage. The panel contains a waste discharge outlet, a

flushing-water inlet, and valves. Couplings—a different size from the water couplings—permit easy attachment and release of hoses. Servicing pipes are sealed with removable blanking caps. Connections are tight to prevent leakage.

A crew empties the sewage by gravity flow through a large flexible hose into a cart or truck, flushes the aircraft sewage container with water from the cart or an auxiliary cart, and pumps fluid chemical into the toilet tank for recharging.

The carts with waste-receiving, flushing-water, and deodorant tanks for ground servicing are maintained separately from drinking water and food service equipment, by a separate crew.

Sewage Retention Capacity

The sewage retention capacity of toilet tanks depends on the number of passengers carried and the duration of the flight. For design purposes, the rate of body waste production per hour per person is estimated at from 0.014 to 0.019 gallon. Dejecta from airsick passengers is not overlooked in estimating waste retention capacity of toilets.

The volume of tanks is increased commensurately with seating capacity and length of flight.

Rounded corners and smooth seams and joints facilitate cleaning of toilet tanks. With ex-

Third Antibiotics Symposium

These are abstracts of a few papers from the third annual Symposium on Antibiotics, held November 2-4, 1955, in Washington, D. C., under the sponsorship of the Food and Drug Administration and in collaboration with the journals, *Antibiotics and Chemotherapy* and *Antibiotic Medicine*. Eleven concern penicillin V. Three deal respectively with antibiotic therapy of sleeping sickness, venereal diseases, and virus diseases.

The proceedings of the symposium have been published in the *Antibiotics Annual, 1955-1956*, issued by Medical Encyclopedia, Inc., 30 East 60th Street, New York 22, N. Y.

Antibiotics in the Treatment of Virus Diseases

The role of antibiotics in the treatment of bacterial diseases has been fairly well delineated. With respect to virus diseases, however, the role of antibiotics still greatly needs clarification.

Four factors contribute to the problem:

1. Accurate diagnosis is difficult, and antibiotics are used on the chance that a particular illness may be of bacterial rather than of viral origin.

2. Confusion arises from the classification of Chlamydozoaceae with the true viruses.

3. A widespread belief prevails that antibiotics will at least be useful in preventing secondary bacterial infection.

4. There is an unjustified assumption that "at least antibiotics can do no harm."

Evidence suggests that the use of antibiotics may actually delay recovery in the following diseases: influenza, the common cold, herpangina, poliomyelitis, measles, and mumps.

Smallpox, chickenpox, and herpes zoster are virus diseases in which antibiotics may be helpful because of their effects upon secondary bacterial infection.

The need for further controlled studies is stressed.

—BARBARA MOULTON, *Division of Medicine, Food and Drug Administration, Washington, D. C.*

Erythromycin Therapy of Venereal Diseases

Although penicillin is the antibiotic of choice in therapy of most venereal diseases, the increasing incidence of hypersensitivity to this agent necessitates that other antibiotics be evaluated for their efficacy in treating venereal diseases in patients known to be sensitive to penicillin. Erythromycin was selected because its in vitro activity most closely parallels that of penicillin.

Health Service standards are a contribution toward attainment of this objective.

PHS Staff Announcement

Abraham W. Fuchs, chief of the milk and food program of the Public Health Service from 1940 to 1952, retired on March 1, 1956, after 39 years with the Service, 26 of them as an engineer officer of the commissioned corps.

For the past year, Mr. Fuchs has been chief of the Field Party, United States Operations Mission, Kingston, Jamaica. He has returned to Jamaica as an adviser on environmental sanitation for the International Cooperation Administration.

In a distinguished career with the Public Health Service, Mr. Fuchs helped State and local agencies to develop milk and food sanitation ordinances and codes and to initiate cooperative programs with industry for the improvement of the sanitary quality of milk supplies. During World War II, his atten-

tion was directed toward adequate milk supplies for critical defense areas and demonstration classes for food handlers. His research focused on sanitary design and adequacy of pasteurization equipment. He developed basic design criteria for leak-protected valves on vat pasteurizers.

From 1952 to 1955, Mr. Fuchs was chief of the Health Division, United States Operations Mission to Israel. The Association of Milk & Food Technology awarded him its citation award last October. He had served as an associate editor of its journal since 1947, as president of the association in 1949, and as a member of the executive board for 6 years.

Mr. Fuchs obtained his civil engineering degree with a major in sanitary engineering at Cornell University in 1913.

all times tested. This was accompanied by an increase in the percent of positive blood samples taken at 6 and 8 hours after a single dose. A twofold increase in the amount of penicillin V acid in capsule form gave proportionately higher blood concentrations 1 hour after administration and slightly higher after 2 hours and 4 hours. Thereafter, the penicillin blood concentration did not increase above that of the lower dose. The number of subjects showing a penicillemia at this higher dosage was the same as that for the lower dosage with the possible exception of the fourth hour, where the difference between the lower dose and the higher dose rose from 82 to 100 percent positive.

Benzathine penicillin V, both tablets and oral suspension, produced significantly higher blood concentrations than comparable doses of penicillin G for the first 4 hours. Thereafter, benzathine penicillin G gave significant penicillin concentrations for 6 to 8 hours in 50 percent of the subjects, while benzathine penicillin V blood concentrations gave only 10 percent positive after 6 hours and were substantially negative after 8 hours.

Blood Levels in Patients Receiving Oral and Intramuscular Penicillins: 24-Hour Study

This study, at the Robert W. Long Hospital, Indiana University Medical Center, was designed to compare blood levels of penicillin V with penicillin G and aqueous procaine penicillin G.

Six patients were given penicillin G in capsules, 400,000 units orally at 0, 6, 12, and 18 hours. Penicillin blood levels were determined at intervals.

After 2 days, the procedure was repeated using the same unit dosage schedule with penicillin V capsules.

Forty-eight hours later, the six patients were given one intramuscular injection of aqueous procaine penicillin G, 400,000 units, and again penicillin blood levels were determined at intervals.

The blood levels of penicillin V compared favorably with the other two penicillin preparations.

—WILLIAM E. SYMON, *Indiana University Medical Center, Indianapolis.*

Comparative Clinical Laboratory Studies: Penicillin V and Penicillin G

Thirty healthy, ambulatory subjects were given equal amounts of penicillin V or penicillin G orally. The material was ingested in the fasting state and following a standard meal. Blood penicillin concentrations were determined at intervals for 8 hours, using a twofold tube dilution technique. When concentrations of penicillin V and penicillin G were compared directly, whether the subject was fasting or not, early levels with penicillin V were achieved which were maintained higher and longer than with penicillin G. Analysis of the data expressed as total penicillemia per 8-hour period revealed that with or without food, penicillin V produced greater blood penicillin concentrations than did penicillin G. There was only a 16-percent difference in penicillin V concentration when it was given fasting or with food. Penicillin V in the fasting state also produced a 61 percent greater concentration than did fasting penicillin G. Penicillin V given with food showed a penicillemia 224 percent greater than penicillin G taken with food. Furthermore, even when penicillin V given with food was compared to penicillin G in the fasting state, 38 percent greater penicillemia values were obtained with penicillin V than with penicillin G.

Effectiveness in Acute Gonorrheal Urethritis

Advantages inhere in both oral and parenteral medication. The choice depends upon the circumstances at hand. The advantages that an oral preparation of penicillin offers over the intramuscular injection are primarily those of convenience and a decreased possibility of sensitization or allergic response. There is therefore

Initially, consecutive patients received erythromycin by mouth. The majority had gonorrheal urethritis. Of 132 patients receiving a total dosage of 0.8 to 1.2 gm., good clinical results were obtained in 114, indifferent in 10, and poor in 8. Fewer cases of nonspecific urethritis and chancroid were available. The results with much larger doses were not striking. The bacteriological results in the cases of gonorrhea were in close agreement with the clinical results.

Another group, all of whom had gonorrhea, received 100 to 200 mg. of erythromycin intramuscularly. Of the 88 patients studied, good clinical results were obtained in 77, indifferent in 5, and poor in 6. More detailed analysis of these data reveals the best results to be in those receiving larger doses.

It appears that erythromycin is a satisfactory substitute for penicillin, especially when given intramuscularly in adequate dosage.

—THOMAS H. HAIGHT, *department of medicine, University of Oklahoma School of Medicine and University Hospitals, and the Prevention and Control Center, Oklahoma City.*

Stylomycin in Human Sleeping Sickness: 17-Month Followup

Fifteen cases of sleeping sickness (*Trypanosoma gambiense*) were treated with stylomycin (puromycin) for 7 to 10 days. The daily dosage used was 1 to 2.25 gm., the total per patient ranging from 9.5 to 13.5 gm. Clinical diagnosis was confirmed by blood cultures (Weinman's medium modified by Henraard and Peel as recommended by Neujean and Evans), cerebrospinal examinations, and microscopic examination of material from the lymph glands. Periodic controls were carried out in the same manner.

Before treatment, material aspirated from the lymph nodes of all patients showed trypanosomes, all spinal fluids were abnormal, and 11 patients yielded positive blood cultures. At the last control, 17 months after treatment ended, 10 patients were negative, 4 relapsed during the first 6 months, and 1 presented

abnormal spinal fluid without any other laboratory sign of the disease.

PENICILLIN V

Blood Concentrations Following Oral Administration and Comparison With Penicillin G

Penicillin V acid in tablet and capsule forms and benzathine penicillin V as tablet and oral suspension have been administered orally to a large number of human subjects. The penicillin blood serum concentrations were determined 1, 2, 4, 6, and 8 hours after a single dose. Crystalline penicillin G potassium or benzathine penicillin G in similar dosage forms were also tested. Tablets or capsules containing 200,000 units of penicillin V acid produced significantly higher blood concentrations than comparable penicillin G preparations. The highest initial blood concentration was given by penicillin V acid capsules 1 hour after administration. Thereafter, the capsules and the tablet formulation gave the same penicillin blood concentrations.

The average concentration of penicillin in the serum 1 hour after the administration of penicillin V acid tablets was 0.884 unit per milliliter, while potassium penicillin G tablets gave only 0.578 unit. Penicillin V acid in capsules given to 50 subjects yielded an average blood concentration of 1,098 units per milliliter 1 hour after administration, while potassium penicillin G in capsules gave only 0.699 unit. The duration of the penicilemia was the same for both penicillin V and penicillin G in either dosage form. Detectable penicillin blood concentrations were found in more than 80 percent of the subjects for 4 hours, and in about 40 percent for 6 hours with either penicillin V or G.

An increase of two and one-half times in the dose of penicillin V acid in tablet form gave proportionately higher blood concentrations at

pendence on metabolism (Clowes and others). Inactivation of penicillin G (benzylpenicillin) and penicillin V (phenoxymethyl penicillin) was examined on liver slides of guinea pigs, using the Warburg apparatus. Inactivation was found to be anaerobic and aerobic, increasing with the amount of penicillin concentration. Investigations with activators, inhibitors, and metabolites show that there is an adaptive ferment which is built up under the influence of penicillin and with use of metabolic energy.

—K. H. SPRYZ, *University Clinic, Vienna, Austria.*

Serum Penicillin Concentrations Following Oral Administration

Capsules containing 200,000 units of penicillin V and commercial 200,000 and 500,000 unit tablets of penicillin G were administered with respect to meals to adults with no evidence of cardiac, renal, or hepatic disease. Serum penicillin concentrations were determined by the *Sarcina lutea* disc-plate method and serial two-fold tube dilution technique. Zone diameters with the plate method were somewhat smaller with penicillin V than with penicillin G and were usually not obtained at concentrations of 0.03 unit per milliliter.

Mean serum concentrations at 1/2, 2, 4, and 8 hours, following doses of 400,000 units of penicillin G were 1.0, 0.88, 0.38, and 0.16 unit per milliliter, respectively, and following penicillin V, same doses, were 0.57, 1.46, 0.49, and 0.08 unit per milliliter, respectively. Eight hours after administration, 12 of 15 patients receiving penicillin G had levels of 0.03 unit per milliliter, or greater, contrasted with 6 of 12 patients receiving penicillin V.

Mean serum penicillin concentrations at the same intervals following 1 million unit doses of penicillin G were 1.31, 1.19, 0.32, and 0.14 units per milliliter, and those following penicillin V, same doses, were 1.83, 2.44, 1.3, and 0.27 units per milliliter. Twelve of fourteen patients receiving penicillin G had levels of 0.03, or greater, 8 hours after administration as compared with 5 of 7 patients receiving penicillin V.

Penicillin concentrations of the serum samples were relatively stable in the case of both

penicillin G and penicillin V at -20°C ., but in the serum penicillin V showed considerably more rapid deterioration than penicillin G at 10°C .

Additional pharmacologic data is being accumulated.

—HERBERT LINDEN, SYDNEY FINEGOLD, and WILLIAM L. HEWITT, *departments of medicine of the University of California Medical School and of the Veterans Administration Center, Los Angeles.*

Some Observations as to Solubility and Stability

Comparisons are made between penicillin V acid, potassium penicillin G, potassium penicillin V, benzathine penicillin G, and benzathine penicillin V with respect to solubility and stability of suspensions and solutions at various pH levels over definite periods of time.

In vivo tests made include comparisons of penicillin V and potassium penicillin G in mouse protection tests against virulent type 1 pneumococci, serum concentrations in chickens following oral administration of the same two penicillins, and human serum concentrations resulting from parenteral injection of the benzathine salt of phenoxymethyl penicillin (penicillin V).

—WILLIAM ELIAS and H. JOSEPH MERRION, *Wyeth Laboratories, West Chester, Pa.*

Some Properties Such as Stability

Phenoxymethyl penicillin (penicillin V) is more stable than benzylpenicillin at $\text{pH} < 6.5$. At higher pH the condition is the reverse. There is a relatively rapid inactivation of penicillin V in serum. The in vitro activity of penicillin V against strains of *Staphylococcus aureus*, beta hemolytic streptococcus, and pneumococcus in our experiments is the same as that of benzylpenicillin. Against a strain of a non-pathogenic *Staphylococcus albus*, penicillin V was 80 percent more active than benzylpenicillin. The reason for this is not known.

Because of its physicochemical properties, penicillin V is suitable for oral administration.

a need for an oral preparation of penicillin, one that will not be destroyed by the gastrointestinal pH and that will be readily absorbed, giving adequate body fluid and tissue concentrations.

Penicillin V (phenoxymethyl penicillin) is such a preparation and it has been reported to be effective in the treatment of certain diseases caused by penicillin-susceptible organisms.

The results obtained to date in our experience with a small number of patients, summarized below, indicate that 1.8 million units is the minimal dose for use in this infection and that a somewhat higher dose may be more effective.

Total dosage (units)	How administered	Num- ber of patients	Cures	Fail- ures
800,000	400,000 twice daily	5	0	5
1,200,000	800,000 initially	4	1	3
1,200,000	400,000 at 6 hours	3	1	2
1,800,000	600,000 thrice daily	10	8	2

It appears, therefore, that penicillin V administered orally may be used in treatment of gonorrhea. The study, the methods and procedures of which have been described elsewhere, is being continued.

—MILTON MARMELL and AARON PRIGOT, *Departments of Pathology and Surgery and Department of Hospitals, New York City.*

Pharmacologic and Toxicological Studies

Penicillin V (phenoxymethyl penicillin) has been shown to be more acid resistant and to produce higher blood levels after oral administration in human test subjects than penicillin G. Studies in laboratory animals have proved the safety of penicillin V and have confirmed the increased absorption and blood levels.

The acute toxicities of penicillin V, sodium penicillin V, and sodium penicillin G have been compared following administration to mice by several routes. The LD₅₀'s ± standard error in milligram per kilogram were: for penicillin V, intraperitoneally 1,351 ± 68, subcutaneously and orally greater than 4,000; for sodium penicillin V, intraperitoneally 2,281 ± 74, subcutaneously 2,440 ± 66 and per os greater than 4,000; and for sodium penicillin G, intraperitoneally 3,314 ± 146, subcutaneously and orally greater than 4,000.

Rats fed diets containing up to 2 percent penicillin V for 2 months gained weight and showed no visceral or hematopoietic damage. Dogs that received daily doses of 200 milligrams per kilogram for the same period also remained normal.

In dogs, the renal clearance was slightly lower for penicillin V than for penicillin G. The secretion of penicillin V by the renal tubules was inhibited by probenecid. Penicillin V was bound by plasma protein to about the same extent as penicillin G.

Blood levels have been determined in several species of experimental animals following oral administration. Penicillin V produced higher levels than penicillin G in most instances.

—ROBERT C. ANDERSON, C. C. LEE, H. M. WORTH, and K. K. CHEN, *Lilly Research Laboratories, Indianapolis.*

In the Treatment of Subacute Bacterial Endocarditis

Three cases of subacute bacterial endocarditis (two due to alpha hemolytic streptococci and one due to *Neisseria sicca*) were treated with oral penicillin V. The dose was two million units every 4 hours.

Penicillin V blood levels (*Sarcina lutea* cup-plate method) ranged between 5.6 and 20 units per milliliter of serum.

One patient was treated for 42 days with a total of 508 million units of penicillin V with clinical and bacteriological remission.

Two of the three cases exhibited clinical relapse after 1 week of treatment. In both cases multiple blood cultures remained sterile. The addition of streptomycin (2 grams per day) to the therapeutic regimen resulted in remission.

No untoward reaction to penicillin V at this dose level was encountered.

—E. L. QUINN, J. M. COLVILLE, F. COX, and J. TRUANT, *Infectious Disease Clinic, Henry Ford Hospital, Detroit.*

Inactivation in Tissues and Body

All of the administered penicillin does not appear in urine. Loss is mainly due to inactivation in tissues, especially the liver, with de-

pendence on metabolism (Clowes and others). Inactivation of penicillin G (benzylpenicillin) and penicillin V (phenoxymethyl penicillin) was examined on liver slides of guinea pigs, using the Warburg apparatus. Inactivation was found to be anaerobic and aerobic, increasing with the amount of penicillin concentration. Investigations with activators, inhibitors, and metabolites show that there is an adaptive ferment which is built up under the influence of penicillin and with use of metabolic energy.

Against a strain of a non-pathogenic *Staphylococcus albus*, penicillin V was 80 percent more active than benzylpenicillin. The reason for this is not known.

Because of its physicochemical properties, penicillin V is suitable for oral administration.

After single oral doses of penicillin V, the concentration in serum during the first 3 hours after the administration is 2 to 3 times greater than that achieved with the same amount of benzylpenicillin. The concentration in serum then falls more rapidly than when benzylpenicillin is administered. After a single oral dose of 0.30 gm. of both penicillins the serum concentration is the same 6 hours after the administration. Lower stability at pH > 6.5 and greater inactivation, by serum, of penicillin V than of benzylpenicillin may be the explanation of this. When penicillin V is given together with probenecid the concentration in serum is twice that obtained with the same dose of penicillin V alone. Furthermore, the period of time during which an effective penicillin concentration is present in the blood is prolonged. An oral dose of 0.12 gm. of penicillin V and 0.7 gm. of probenecid once every 8 hours maintains continuously a concentration in serum that is effective for the majority of infections caused by bacteria sensitive to penicillin.

—N. A. DIDING and A. RUNE FRISK, *Stockholm, Sweden*.

Toxicological Properties of Various Forms

Acute and chronic toxicity of penicillin V was investigated in mice, rats, guinea pigs, rabbits, and dogs; and the effects following various

routes of administration were compared with those of procaine penicillin G, potassium penicillin G, and N, N'-dibenzylethylenediamine (DBED) dipenicillin G. After oral, intramuscular or intra-abdominal administration, the toxicity of penicillin V and DBED dipenicillin V compared favorably with that of the other penicillin forms similarly administered. Intravenously, penicillin V, it was found, could be administered rapidly without untoward effect and when compared to potassium penicillin G administered at the same rate, the latter was approximately 8 to 10 times more toxic. The mean gain in weight of rats fed 0.1 or 0.2 percent penicillin V or DBED dipenicillin V in the diet for 8 weeks was similar to that of the controls fed only the basal diet. Neither dogs administered intramuscularly or orally 100 mg./kg. daily, nor rabbits intramuscularly administered 20 mg./kg. for 8 weeks exhibited any unusual behavior or serious alterations in their mean body weights. Periodic hematological studies and microscopic examination of tissues following complete autopsies at the termination of the experiments revealed no significant changes as a result of the penicillin V or the DBED dipenicillin V.

Medical Review Bibliography

A Bibliography of Medical Reviews is scheduled for publication in May 1956 by the Armed Forces Medical Library. Arranged by subject, it will contain approximately 800 references to review articles in clinical and experimental medicine and allied fields. All of these have appeared during the calendar year 1955.

Copies of this bibliography will be supplied in the order requests are received by: The Director, Armed Forces Medical Library, Washington 25, D. C.

ESTELLA FORD WARNER

*"No Need for Acclaim . . .
But to Perpetuate
Influence She Generated"*

Dr. Estella Ford Warner, who retired this year after a distinguished career with the Public Health Service, takes to her adobe home in Albuquerque the warm affection, deep respect, and unqualified admiration of all who have known her. Her retirement is not the occasion to pay her tribute, because she does not need acclaim. Although she has been honored many times, honors are superfluous to her. These comments are offered primarily in the hope that they may help to some degree to conserve and perpetuate the influence she has generated.

When Dr. Warner was recruited for the Public Health Service by Dr. Warren Draper in 1932, she was known both here and abroad for her development of State and county maternal and child health services in Oregon. Although she had a flourishing practice in pediatrics in Portland, where she had earned a medical degree at the State university, she took up public health work because of her conviction that "the best road to good child health is preventive medicine on a community basis."

The first woman to enter the commissioned officer services of the United States, Dr. Warner was an important addition to the Public Health Service both as a physician and as an administrator. At all times, she has personified competence of a very high level.

Her direct contributions to public health have been described elsewhere, if all too briefly.

They are an important element in the chronicles of world health progress, and it is to be hoped that some day they will be celebrated in history as they deserve. The strategic value of her work with mothers and children, with indigenous primitive tribes on reservations in the southwest, with families of warworkers housed in trailers and other temporary quarters during the war, with Federal assistance to State health departments, and with expanding health services in Asia is yet to be seen in perspective.

The achievement in itself is impressive. The effects of programs she advanced for malaria control and sanitation in India alone are certain to extend and enrich millions upon millions of lives.

While what she has done commands respect, these achievements are noteworthy as well for the spirit and method of their accomplishment. Perhaps this is best indicated by the fact that of all those men and women who have been assigned to her staff, there are none who speak of having worked "for" Dr. Warner. It is not an affectation when they say they worked "with" her. It is a tacit and grateful acknowledgment of the fact that in every endeavor she created a pervading sense of shared purpose and action.

She took to heart the doctrine that democracy is a way of working as well as a way of living. As a division chief, she demonstrated her characteristic ability to accept and make use of new ideas and methods. Since it was not in her

nature to be authoritarian, she was always as ready to hear from her staff members as to give counsel and guidance.

Her accomplishments have been world enriching, her methods inspiring. She has attained the high goals she set for herself and, in so doing, has established new goals for those who follow.

With such concepts and attitudes, it was to be expected that her office would be the source of creative ideas in public health, that it would be eager to perform real functions rather than to pretend to formal responsibilities, that it would constantly evaluate, and reevaluate, the performance of public health services.

On the eve of her retirement, she was continuing to encourage health workers in foreign missions to write what they observed and what they were doing about public health, in line with her constant wish to focus health concepts on living processes.

If further tribute is to be paid to Dr. Warner by her colleagues, they can do no better than apply her concepts, to be sensitive to public needs, to observe and report what is being done and what can be done, and to proceed in concert to meet public needs as they are understood.

—By LEONARD A. SCHEELE, *Surgeon General, Public Health Service.*

On Rehabilitation

"In Salt Lake City recently, over a 6-month period, half the applicants for public assistance whose need was due to a father's desertion were handled by a trained social worker who stressed the services that would help cure the problem. The other half were handled routinely—their need was established and payments were made, but no special help was given in eliminating the cause of need. At the end of 6 months, assistance payments to the families who had received professional self-help services were 41 percent less than assistance payments to the other families.

"In New York City, over a period of 3 years, a skilled welfare staff focused on a direct effort to return persons to self-support. Of a total of 2,700 cases, involving persons who had been unemployed from 1 to 19 years, 616 were restored to independence as a result of services provided by social workers. The savings in the actual cost of assistance has been \$616,000 per year. But far more important than the savings of tax dollars is the promise of a richer life for human beings.

"In New York State, 3,600 disabled persons were returned to employment and a self-sustaining life through vocational rehabilitation last year. These people were earning less than \$1.5 million a year when they started on the road to self-support. The first year after rehabilitation, their earnings were estimated at more than \$8 million—almost a six-fold increase.

"In the Nation as a whole, more than 11,000 of those rehabilitated last year had been receiving public assistance payments. It cost about \$8 million to rehabilitate this group—but in just one year it would have cost almost \$10 million to maintain them on relief. Relief costs generally were stopped and earnings and tax payments were started, but the richest reward from this program is the conversion of misery and despair into hope, dignity, and a productive life."

—MARION B. FOLSOM, *Secretary of Health, Education, and Welfare.* From an address before the Rochester City Club, Rochester, N. Y., March 3, 1956.

In planning community X-ray programs, it is useful to know why some people appear for screening and others stay away. A psychological study suggests three apparently significant factors in the public attitude toward chest X-rays.

Why People Seek Diagnostic X-Rays

By GODFREY M. HOCHBAUM, Ph.D.

MANY well-organized, efficiently handled, and very successful community X-ray programs have been conducted throughout the United States. Yet, even in the most effective ones, various segments of the population have failed to obtain X-rays. There is evidence that these segments include groups in which tuberculosis is highly prevalent.

It is hoped that better knowledge of factors which determine whether or not people obtain chest X-rays will help in planning more effective programs, especially for those unresponsive population groups. With this in mind, the National Tuberculosis Association and the Public Health Service jointly sponsored a study to identify some of these factors.

For this study, intensive personal interviews were held with 450 persons in Boston, 450 in

Cleveland, and 300 in Detroit, all 25 years of age or older. The respondents were selected in each city on the basis of random population sampling. The interviews, each lasting more than 1 hour, were designed to stimulate the respondents to express their opinions as well as their feelings and attitudes concerning psychological, sociologic, and administrative aspects of case finding for tuberculosis. To learn more about opinions, attitudes, and feelings than is usually expressed when only direct survey questions are asked, use was made of various psychological techniques, such as projective questions.

Of the 1,200 persons interviewed in the 3 cities, only 42 percent had voluntarily and without having any signs or symptoms of illness obtained one or more chest X-rays to check for tuberculosis. Another 16 percent stated that they had obtained X-rays voluntarily, but that they had done so because they had noticed symptoms which they thought might be due to tuberculosis. Fourteen percent said they had had all their X-rays either because other persons or groups had pressed them or because the X-rays had been required for one reason or another. A few persons had had X-rays to check for heart trouble or lung cancer rather than for tuberculosis. For about 10 percent who had had X-rays, no consistent and typical pattern could be established. Seventeen percent of the 1,200 persons had never in their lives had an X-ray.

Whether or not a person voluntarily obtains

Dr. Hochbaum is a research psychologist, Behavioral Studies Section, Division of General Health Services, Public Health Service. This article is a modification of a paper he presented at the annual meeting of the National Tuberculosis Association, Milwaukee, Wis., May 25, 1955. It deals with only one set of findings from a study on voluntary participation of the public in tuberculosis case-finding programs. A discussion of all the findings, as well as a fuller description of sampling procedure, study design, and techniques of obtaining data, will be published in monograph form at a later date.

a chest X-ray when given the opportunity is the result of a decision made by him. The fundamental problem with which this research was concerned, therefore, can be expressed by the following questions: Why and under what conditions do people decide to seek chest X-rays when given the opportunity? Why and under what conditions do they decide not to? Since a decision to act still may not result in an act, a further question must be posed: What conditions make it more likely or less likely for people who have decided to obtain X-rays actually to obtain them?

Obviously, many factors must be examined to answer these questions. Some of these are psychological in nature; others, sociologic; and still others, situational. No single factor ever determines by itself whether a person will or will not voluntarily obtain a chest X-ray. Hence, the study was designed to deal with a variety of factors. It was designed, further, not only to identify the factors that influence people to seek diagnostic X-rays, but also to determine how various factors affect each other.

This report is concerned with only one set of factors investigated by the study. These factors, even when considered by themselves, appear to be of particular significance to the question of why people seek diagnostic X-rays. A report to be published at a later date will discuss these factors in relation to several others investigated in the study.

The Three Factors

The first in this set of factors is a person's conviction that he himself could really contract tuberculosis.

The second is a person's conviction that he might have tuberculosis for a considerable period of time without being aware of it—that is, without experiencing any outward symptoms of illness—and that only through a chest X-ray could the fact that he has the disease be ascertained.

Among 798 persons in the sample who had unrestricted freedom and opportunity to obtain X-rays (that is, excluding persons who had had X-rays because they were required to do so and also those who obtained X-rays for reasons not relevant to this analysis), 442 believed that

they could contract tuberculosis and also that X-rays alone would show the presence of the disease at an early stage. Over 80 percent of this group, although feeling healthy and free from any symptoms at the time, had voluntarily obtained X-rays. In contrast, 356 persons either did not believe that they would ever contract tuberculosis or were certain that they would be aware of it if they had the disease. Half of this group either had never had X-rays or had obtained them only after they had noticed what to them seemed suspicious symptoms.

From the nonmedical point of view, this behavior is quite rational. If a person is convinced—rightly or wrongly—that he will never have tuberculosis, it would seem to him a complete waste of time and effort to check on whether he does have it. And if a person is convinced that there will be some sign of illness, some pain or disfunction, as soon as he has become infected, he is also convinced that he could not have tuberculosis as long as he feels completely well. Such a person, too, would regard X-rays as completely unnecessary and would obtain them only when he notices signs which he thinks might be symptoms of tuberculosis.

Briefly, then, the findings indicate that people are likely voluntarily to seek diagnostic X-rays only if they really believe that they might contract tuberculosis and that it would be dangerous to rely on the appearance of outward symptoms.

The third factor is a person's belief that early detection of tuberculosis would decrease the problems and worries which he thinks would arise for him should he ever contract the disease. About 90 percent of 510 persons holding this belief had voluntarily obtained X-rays, a percentage about twice the percentage found among those who did not hold this belief.

Again, this is not at all irrational from the layman's point of view. To the medical profession, early detection means better prognosis or shorter, simpler therapy. But many people were found to worry less about prognosis or difficulty of treatment than about such things as losing their jobs and income, the shattering of their careers, or the financial burden on their families. Many of these people did not feel

that early detection of tuberculosis would do much to alleviate these problems. For them, detection of tuberculosis—early or late—may, with good reason, appear threatening rather than beneficial. They therefore tend to avoid being X-rayed.

In other words, people tend to obtain X-rays only if they feel that by early detection of tuberculosis those problems which they worry about can be avoided or at least considerably decreased.

Of particular interest in a study of why people obtain X-rays are those population groups among whom a relatively high tuberculosis prevalence has been reported but who often show very poor participation in screening programs. In this study, data for two of these groups, older males and people with low incomes, were analyzed.

It was found that the three factors described cut across socioeconomic classes and sex and age categories. That is, people who believe they might get tuberculosis, those who do not rely solely on symptoms as a stimulus for seeking X-rays, and those who see benefits for themselves in early detection of tuberculosis are likely to obtain X-rays voluntarily regardless of their economic status, their sex, or age. One thing that characterized the nonparticipating groups was that fewer persons in these groups held those beliefs.

Knowledge and Action

In looking over these three factors, one may be tempted to conclude that many people still are not informed about tuberculosis and about the role of X-rays. But such a conclusion is not justified. What we are dealing with here is not merely a matter of information. It is a matter of real belief and of a conviction on the part of people that such information applies to them personally and that it is important to them as individuals.

Without question, a person must know what to do, when to do it, and how to do it before he can take action. But merely knowing these things will usually be insufficient to elicit the action to which they relate. Each of us keeps a storehouse of knowledge about things to do for our own health and welfare. But there is

a gap between having this knowledge and applying it in our own behavior. We learn to give the correct answers to questions long before we apply the information in voluntary action.

In view of these facts, it is not surprising that, although most people in the sample were able to give correct answers to direct informational questions, many of them still had never voluntarily applied this information by obtaining X-rays.

The following will illustrate this. During the interview, respondents were asked a direct informational question to see whether they knew that chest X-rays can detect the presence of tuberculosis before the patient becomes aware of outward symptoms of the disease.

Over 80 percent of the respondents were able to give correct answers to this question although many of them had never voluntarily obtained X-rays. Later in the interview, this subject was taken up again through a number of indirect, or projective, questions. These were designed to reveal beliefs and convictions, rather than merely factual information.

Analysis of the answers given to these projective questions yielded an interesting finding: Many of the respondents who had proved themselves fully informed concerning the fact that one can have tuberculosis without knowing it betrayed in their responses that they, to at least some degree, felt that they themselves would know if they had tuberculosis. Only about 35 percent of 543 such respondents had ever voluntarily obtained a chest X-ray without first noticing signs or symptoms of illness. Among those in whom this belief was especially strong, this percentage drops to about 20.

On the other hand, X-rays had been obtained voluntarily by 80 percent of the persons whose responses to the projective questions indicated that they believed fully that they themselves could have tuberculosis for a considerable period of time without knowing it.

Conclusion

It should be emphasized again that this report deals with only three of the many factors that determine whether a person decides to obtain a chest X-ray and whether he follows up

his decision with appropriate action. Additional factors are being investigated in this study, and the results should further increase our understanding of the nature of voluntary health behavior.

To be of real value, however, the findings of

this study must be tested in actual practice under controlled conditions. Such coordination between research and program application is a must if research is to pay maximum dividends in ever-increasing sound health practices by the public.

Pathological and Laboratory Services To Hospital Patients in Iowa

Of interest to hospital associations and administrators, as well as to physicians, pathologists, and laboratory technicians, is a recent decision by a district court of the State of Iowa, involving the provision of technological services to hospital patients. The case was that of *Iowa Hospital Assn., et al. v. Iowa State Board of Medical Examiners, et al.*, District Court, Polk County, decided November 28, 1955.

A group of some 30 nonprofit hospitals had brought an action for declaratory relief following the issuing of an opinion by the State attorney general. The major issue, as defined by the court, was whether "in purveying to patients . . . medical services in the form of laboratory procedures and X-ray procedures for compensation" the hospitals were engaged in "the illegal corporate practice of medicine."

The court ruled that they were so engaged and concluded, in addition, that under the practices described the pathologists or radiologists permitting a hospital to bill for medical services in the name of the hospital, without obtaining patient consent, violated the Iowa statute prohibiting fee splitting.

The Iowa State Hospital Association and the Iowa Medical Society were arrayed against each other in this litigation. The first joined with the hospitals as a plaintiff in the action, and the medical society intervened in behalf of the defendants which, in addition to the State

attorney general, included the Iowa State Board of Medical Examiners and the Iowa Association of Pathologists.

The arrangements for supplying pathological and laboratory services which had been practiced by the plaintiff hospitals and which the court condemned as violating the Iowa statutes are set out in detail in the court's findings. They were of long standing in the State and do not differ essentially from procedures commonly followed elsewhere. The opinion recognized that the facilities of pathology and X-ray laboratories are essential parts of a modern hospital that the plaintiff hospitals could continue to maintain. Further, it expressed the belief that the supplying of such services could be worked out "on the local level and within the law." The extent and nature of the required adjustment, however, were not spelled out in the opinion although changes by the hospitals in contractual arrangement with those providing services and with the patients would seem indicated.

The case has been appealed to the Supreme Court of Iowa. While the statutes involved are those of a particular State, the litigation is of unusual interest since this appears to be the first reported case in which nonprofit hospitals by such arrangements have been held in violation of medical practice acts.

A review of the experience of the metropolis during the pre-war, war, and postwar periods points to the need for continuing control programs.

Venereal Disease Control in New York City

By THEODORE ROSENTHAL, M.D., and JULES E. VANDOW, M.D.

THE recent downward trends in the incidence and prevalence of venereal disease in New York City have been observed also in other parts of the United States (1-3). Confirmatory evidence from the autopsy table is provided by Bell (4), who found marked declines in mortality due to syphilis in the past two decades. Improved methods of diagnosis, treatment, public health education, and administrative control have undoubtedly contributed to this reduction of the venereal disease problem.

Previous reports (5-9) have described in detail the character of the New York City venereal disease control program and have presented statistical data on its progress. The present report completes this information through 1954, thus providing a continuing record from 1938.

Early Control Activities

The historical background of the present venereal disease control program in New York City may be of interest. The first action in dealing with the venereal diseases as a public health problem in the city was initiated by

Biggs in 1912 (10). His program embraced the following pioneer steps:

1. Making syphilis and gonorrhea reportable diseases.

2. Offering diagnostic laboratory tests (including serologic tests for syphilis) for venereal disease to all physicians in the city without charge.

3. Advocating establishment by the health department of special clinics for diagnosis and treatment of venereal disease. (These clinics were for diagnosis and advice only. Five years later, in 1917, treatment was included in the services of the health department clinics also.)

4. Providing special hospital facilities for venereal disease cases.

5. Carrying on an educational campaign against patent nostrums and quackery in the field of venereal diseases. An attempt was made to follow Biggs' recommendations; inadequate staff prevented the full development of this forward-looking program for a score of years.

In 1935, a survey by the American Social Hygiene Association revealed the startling information that there were over 1 million men, women, and children in New York City suffering with syphilis or gonorrhea (378,000 with syphilis and 750,000 with gonorrhea), one-fifth of whom were infectious. The survey also revealed that 700 residents of New York City were being admitted annually to State hospitals for general paresis and other syphilis of the central nervous system.

Dr. Rosenthal is assistant commissioner of the City of New York Department of Health, New York, N. Y. Dr. Vandow is chief of the division of social hygiene, bureau of preventable diseases, and is also a special consultant to the Public Health Service.

During the period 1912-35, venereal disease control in the New York City Department of Health was a responsibility of the bureau of preventable diseases. In 1935, based on the

survey and recommendations of the American Social Hygiene Association, a separate bureau of social hygiene was created to administer the venereal disease control program. Under a full-

time bureau director, many of the recommendations made in the survey report were carried out. Among the most important were the following:

1. Increase of laboratory services to aid physicians in the diagnosis of persons infected with venereal diseases.
2. Establishment of a consultation service to advise practicing physicians in the handling of their venereal disease patients.
3. Expansion of case-finding and case-holding services.
4. Utilization of all available media to educate and inform the public as well as to provide technical instruction to physicians, nurses and others.
5. Improvement in reporting procedures.
6. Provision of free drugs to hospitals, clinics, and private physicians.
7. Cooperation with other departments of city, State, and Federal governments and with voluntary institutions and professional groups.

In addition, a comprehensive research program was carried out, including investigations on intensive treatment methods in early syphilis, evaluation of drugs in the treatment of syphilis, and fundamental studies in lymphogranuloma venereum and granuloma inguinale.

Modern Control Program

Several years were required to familiarize physicians and personnel in hospitals, clinics, and laboratories with their basic responsibilities concerning morbidity reporting. For this reason, morbidity statistics for the venereal diseases prior to 1938 are not completely reliable; as a matter of fact, syphilis cases were tabulated merely on the basis of positive serologic reactions in the laboratories of the health department. Since 1938, however, the morbidity reporting system has been on an efficient and reliable basis, eliminating to as great an extent as possible all duplications. Specially trained

Figure 1. Newly reported syphilis and gonorrhea cases, New York City, 1938-54.

physicians have been available since 1935 to consult with practitioners throughout the city on any phase of their venereal disease problems. This has tended to improve accuracy and completeness in reporting.

Local public health regulations contained in section 88 of the New York City sanitary code, supplemented by article 17B of the New York State public health law, provide for control of infected persons, morbidity reporting by physicians and institutions, and reporting of positive laboratory findings by clinical laboratories.

The Prewar Period, 1938-41

Tables 1 and 2 present in detail the number of reported cases and rates per 100,000 population for each venereal disease reported in New York City during the period 1938-54. The year 1938 marks the first year that these data may be considered to be reliable. In that year, 37,077 cases of syphilis were reported, a rate of 503.6 per 100,000. In the same year, almost 13,000 cases

of gonorrhea were reported, representing a rate of 175.7 per 100,000.

From 1938 to 1941, the number of reported cases of syphilis steadily declined to 27,194, the rate falling to 362.1 per 100,000. There had been close cooperation with the Selective Service System for distribution of social hygiene literature to prospective registrants. Educational activities had been increased throughout the city and every possible aid, such as films, lantern slides, posters, and pamphlets, had been made available to the various military installations located within the city.

Syphilis was declining in New York City at a fairly rapid rate even before the advent of penicillin. It is felt that this decline resulted from the comprehensive control measures that had been in effect since 1935. Primary and secondary syphilis declined almost 50 percent in this same period.

During this period, there was little change in the reported number of cases of gonorrhea.

Figure 2. Syphilis cases, by stage of disease, New York City, 1938-54.

Figure 3. Newly reported cases of chancroid, granuloma inguinale, lymphogranuloma venereum, and nonspecific urethritis, New York City, 1938-54.

Apparently control measures that were effective against syphilis had little effect against gonorrhea. The same could also be said for chancroid since this disease appeared to be increasing steadily each year so that, in 1941, the rate was 5.7 per 100,000, more than two and one-half times higher than in 1938.

It may be concluded, nevertheless, that the expanded venereal disease control program that was put into effect in 1935 was an important factor in preventing a rise in the incidence of syphilis and gonorrhea during the period of military and industrial mobilization just preceding the actual outbreak of World War II.

The War Period, 1941-45

With the country engaged in a global war, the problems of venereal disease control were multiplied enormously. Because New York City is a great seaport and railroad center, it became an important point of embarkation for

millions of soldiers. Soldiers and sailors flocked to the city nightly from the many nearby military installations. Industrial workers poured into the city by the thousands, attracted by the expanded industrial activity.

Close cooperation was maintained by the city with each branch of the military service. The Armed Forces Disciplinary Control Board was created at this time to secure even closer cooperation with civilian agencies charged with control of prostitution, sale of alcoholic beverages, and related matters. Reported venereal disease contacts of members of the armed forces who had allegedly been infected in the New York area were over 10,000 each year. Every effort was made to locate and secure the medical examination of the persons named as contacts (11), and approximately 60 percent of these were located.

During the war period, primary and secondary syphilis increased over 40 percent and early

latent syphilis increased over 20 percent. Tabulation of morbidity reports indicated early that syphilis was increasing, particularly in the younger age groups. Because of this, control measures were intensified (11). Gonorrhea rates also rose steeply, increasing from 163.7 in 1941 to 234.4 in 1945. The sulfonamides were being used for treatment; penicillin, though known to be effective, was in short supply and was reserved almost exclusively for the armed forces.

The Postwar Period, 1946-54

Following the close of the war, reports of communicable syphilis and gonorrhea continued to mount until peak levels for these diseases were reached in 1946. Since then, there has been a steady drop in reported cases. Some of the important reasons for this falling incidence are utilization of penicillin and other antibiotics, improvements in diagnostic procedures, and intensification of public health control activities. It was fortunate that at this time penicillin became freely available for civilian use. Its value against both syphilis and gonorrhea had already been well demonstrated by a number of studies in military and civilian institutions.

Improvements in laboratory procedures, such as the development of cardiolipin antigen and quantitative tests resulted in more accurate serologic tests for syphilis and better evalua-

tion of the effectiveness of treatment. Improved culture methods were valuable in the diagnosis of gonorrhea, especially in females.

Discussion

A general picture of the reported cases of the venereal diseases in the period 1938-54 may be obtained from figures 1-3. There was little change in the rates for newly reported cases of gonorrhea until 1942, when the rate began to climb slowly. After 1944, a sharp increase occurred, reaching a peak in 1946 about twice as high as that of 1942. For 2 years, until 1948, this high level was maintained. Then, for the next 4 years, the rate steadily fell until in 1952 it was back to about the 1942 level, where it has hovered ever since.

The total number of syphilis cases fell from a rate of 503 in 1938 to 295 in 1945. The fall was steady except for a moderate increase in 1942, when many latent cases were being discovered by medical examination of draftees.

Another increase occurred in 1946 but this was mainly due to an increase in early syphilis cases after the war. Again, the total syphilis figure began to decline, reflecting a decrease in primary, secondary, and early latent syphilis. After 1949, the rate for total syphilis again rose steadily, reaching a plateau in 1952-53. This last increase was due entirely to steadily increasing reports of late latent syphilis which overshadowed the decreasing reports of infectious cases. In 1954, for the first time since 1945, late and late latent syphilis reports fell sharply, producing a decided drop in the total syphilis rates from about 312 in 1953 to 241 in 1954.

The relationships of the various stages of syphilis to each other are better seen in figure 2. From a rate of 68.6 in 1938, primary and secondary syphilis fell to a rate of 39.4 in 1941. These cases then increased each year throughout the war into the postwar year 1946, when they reached their peak, a rate of 78.5. Since

this high point, the incidence has fallen each year during the succeeding 8 years. As the chart reveals, the descending curve has almost flattened out over the past 4 years. Nevertheless, the rate of 7.7 in 1954 is less than half the 1950 rate of 16.5.

The curve for early latent syphilis almost exactly parallels that of primary and secondary syphilis from 1940 to 1954, except that the rates for early latent syphilis run at a slightly higher level than those for primary and secondary syphilis. No attention should be paid to the 1938-40 rates for early latent syphilis, since during this period early latent syphilis was referred to as early syphilis and included only latent cases of less than 1 year's duration. Undoubtedly, if cases up to 4 years' duration had been included in this diagnosis, in accordance with accepted practice since 1940, the curve from 1938 to 1940 would be higher than that indicated in the chart.

Except for the year 1942, when there was a slight increase, "other" syphilis (which includes late latent, late, and stage unknown) dropped precipitously from a rate of 393.5 in 1938 to 140.3 in 1945. Thereafter, it rose steadily to a high point of 265.8 in 1953. A "mass street survey" in 1953 uncovered many cases of late latent syphilis, which helped to push the rate up to the highest level recorded since 1942. Many of these cases undoubtedly were acquired during the war years. In 1954, more than 5,000 fewer cases of late and late latent syphilis were reported than in 1953, the rate falling to 201.7.

Table 3 indicates the number of cases of syphilis and gonorrhea reported annually from each of the three reporting sources during 1940-54. Also indicated are the percentages of the total number of syphilis and gonorrhea case reports received annually from these reporting sources.

Figure 3 shows the rates for the minor venereal diseases, and indicates the postwar peak for these diseases.

Nonspecific urethritis is not reportable in New York City. In 1951, because of the relative increase of cases, it was decided to admit and treat these patients in health department clinics. Figure 3, therefore, by no means reveals the true incidence of this disease, since the rate refers only to patients admitted by health de-

partment clinics. In 1953, nonspecific urethritis made up 11.2 percent of the total number of cases of urethritis in males seen in these clinics, which, in 1954, was 15.3 percent of such cases.

In 1938, 1,654 cases of congenital syphilis in all ages were reported; 159 were under 1 year of age. There has been a gradual decline since that time so that in 1954, 390 cases of all ages were reported, with only 33 under 1 year of age (table 4 and fig. 4).

A parallel picture is seen in syphilis of the central nervous system. A tabulation of admissions of New York City residents to State mental hospitals for syphilis of the central nervous system shows a gradual decline. In 1933, 732 cases were admitted; a progressive reduction in numbers ensued each year, with 167 being admitted in 1953 (table 5).

Another index of the decline in venereal disease prevalence is furnished by the records of the Women's Court, where all women arrested on charges of prostitution are examined for venereal disease.

Table 5. First admissions from New York City to New York State civil hospitals diagnosed as syphilis of the central nervous system, fiscal years 1933-53

Fiscal year	General paresis and other syphilis of the central nervous system		
	Males	Females	Total

Figure 5. Number of cases of primary and secondary syphilis, all syphilis, and gonorrhea diagnosed in all women coming to the Women's Court, New York City, 1943-54.

A glance at figure 5 reveals the progressive decline in both syphilis and gonorrhea. In 1943, 34.8 percent of the women arrested were found infected with gonorrhea and 15.8 percent with syphilis. In 1954, 5.5 percent had gonorrhea, whereas only 3.4 percent were found to have syphilis (table 6).

The changing trends in case reporting, as seen in table 1, are produced by such conditions as the marked decline in lesion syphilis, the increase in latent syphilis, and the increasing use by the private practitioner of such effective remedies as penicillin and other antibiotics. In the diagnosis of syphilis, the laboratory plays a vital role. All laboratories in the city are required to report positive findings to the health department. This is an important factor in the completeness of syphilis morbidity reporting. Unfortunately, the laboratory is not uti-

Table 6. Venereal disease among women examined in Women's Court, New York, N. Y., 1943-54

Year	Number examined	Percent infected		
		Syphilis	Syphilis and gonorrhea	Gonorrhea
1943-----	4,595	10.0	5.8	29.0
1944-----	4,448	9.1	5.5	28.4
1945-----	4,814	9.4	6.5	25.7
1946-----	4,038	14.7	6.6	16.9
1947-----	3,588	14.8	5.9	18.6
1948-----	3,685	12.9	4.2	17.5
1949-----	3,269	13.1	2.8	13.6
1950-----	2,999	8.3	1.2	10.8

1954-----	2,448	2.9	.2	5.6

lized to the same extent for the diagnosis of gonorrhea, a fact which helps to explain the paucity of gonorrhea morbidity reports from private practitioners.

Conclusions

Reductions in reported cases of early syphilis, gonorrhea, and other venereal diseases have occurred in New York City since the end of World War II. Our public health control programs have skillfully combined community resources to include in our venereal disease combat teams the private practitioner of medicine; personnel of hospitals and clinics; educational institutions; social and welfare agencies; the voluntary organizations, such as the New York Tuberculosis and Health Association, Inc., and the American Social Hygiene Association; the clergy; and the Armed Forces, coordinated by the official health agencies and with, above all, an informed public.

Further reductions in venereal disease incidence will be difficult to achieve in an area such as New York City, which is not only a focal point for traffic from all parts of the United States but, in addition, is a global seaport and airport. Population movement from within the country, coupled with the increasing international traffic into the area, constitute problems beyond any local public health control.

These and other special problems peculiar to a great metropolis point to the necessity for

maintaining a vigorous program for the continued control of venereal disease.

A Pre-Administration Curriculum in a School of Public Health

By KEITH O. TAYLOR, M.B.A.

WE ARE currently faced with the need for well-qualified administrators in the health fields. The selection of persons for such positions is difficult. The hospital field, in particular, has only in fairly recent years established graduate training for persons desirous of entering this field. The first course in hospital administration was started at the University of Chicago in 1934, but there are now 13 courses in schools with membership in the Association of University Programs in Hospital Administration.

The hospital field had the advantage of a major study of problems of hospital administration and university curriculums to meet the needs in this field. The initial major study was conducted from 1945 to 1948 by a Joint Commission on Education with Charles E. Prall as director. This study was sponsored by the American College of Hospital Administrators and the American Hospital Association and received financial support from the Kellogg Foundation. The final reports were issued in 1948 and helped to focus attention on areas which required emphasis in the academic and preceptorship periods. One subsequent study

and review has already been undertaken in this field.

Basic Recommendations

The Prall study (1), although it did not give major attention to undergraduate preparation for those desiring to enter the graduate field, did make certain rather general recommendations. It suggested that extensive specialization at the undergraduate level is probably neither necessary nor wise and that a student should aim toward a well-rounded general education. But the recommendation goes on to say that "the idea of a broad basic education should not be confused with an excessive scattering of effort." More specifically, the report says:

"Students who are completing requirements for their first degree often ask what work will be most useful if later they seek admission to the courses in hospital administration. A complete answer to this question requires knowledge of the individual's past training, special qualifications, and job experience. What is offered here must, therefore, be considered in the nature of general guidance.

"If the student is not completing a major in the social studies or psychology, one or more senior college courses in each of the following should be suggested: economics, sociology or government, psychology. If he has had only the minimum requirement in science, some ad-

Mr. Taylor has been associate director of the course in hospital administration of the University of California School of Public Health, Berkeley, since 1950.

vanced work in either the biological or the physical sciences would prove to be valuable. There are circumstances, of course, where a new beginning might be preferable. The individual who has had no recent contact with chemistry or biology is a case in point. A try-out in statistics, if not restricted by prerequisites, and a course in introductory accounting should be included. The last-named is the only subject mentioned thus far as a requirement for admission."

The more recent Olsen report (2) gives added emphasis to the need for more basic preparation in the field of business but, like the Prall report, notes the importance of a well-rounded general education. To the extent to which these prerequisite ideas are correct, it is apparent that such a program might be based in any of several schools, liberal arts, sociology, business administration, to mention a few. It is, however, essential that whatever school is chosen it provide adequate flexibility.

Flexibility in Planning

At the University of California, a program of this nature has been developed in the School of Public Health. The school provides an upper division curriculum. The need for drawing on many interdepartmental disciplines to supplement the fields of major concentration makes flexibility a basic element in the school's curriculum planning.

There was little difficulty, therefore, in establishing a pre-administration program of reasonable breadth, one that could be rather readily tailored to the needs of students who had completed an associate of arts or its equivalent at the college level in their first 2 years.

Some courses at the lower division level are recommended toward advanced work which the student takes after admission to the School of Public Health, but in practically all cases any student entering at the junior year can complete the remaining lower division prerequisites and the upper division requirements within 2 years. Prerequisites include at least 9 units from the social sciences; 12 from the humanities, English, and speech; and a basic biological science, beginning accounting, and a

survey course of the health fields. When possible, a basic law course is recommended at the lower division level. Emphasis at the undergraduate level for the relatively few students who indicate an interest as early as their freshman year is toward a broad educational background and one which will allow them a maximum diversity of selection by the time they are ready finally to choose their upper division school since by that time some students will have found interest in other directions.

Admission Requirements

Selection for admission at the upper division level in hospital pre-administration is rather stringent. All students who apply are interviewed at considerable length by a full-time faculty member of the graduate course in hospital administration and are then referred to the university counseling service for testing and counseling interviews.

Students are normally referred to a local hospital administrator for further interview and assigned brief readings in the field. There are a number of reasons for lengthy consideration at this point. Many students, whether correctly or incorrectly, wish their degree in a major in which the undergraduate degree in itself will provide an entree to specific job situations. The pre-administration major and the bachelor of science degree provide an essentially broad background and not a degree acceptable to hospitals for positions in the field of hospital administration. This is also largely true of alternate selections in the upper division in the areas of public health and medical care pre-administration.

Students who wish to enter the field of hospital administration, therefore, must be prepared to maintain an adequate grade average for acceptance by a graduate school and, in the case of the University of California, must plan on a 3-year program beyond the baccalaureate in order to complete the requirements. Students, moreover, must be provided with the facts that placement in this field, while good, means willingness to go wherever positions are available and that progression in the field requires a continuing growth of the individual over a fairly long period. The rapid changes

in hospitals and related health groups in the last 20 years, the continuing technical, economic, and human relations changes now in process call for administration with breadth and flexibility.

This means that emphasis must be placed on the fact that a considerable measure of the individual's success will depend on his own ability to prove ultimately his leadership qualities. Education can provide stimulus for the individual, provoke curiosity, and give a student the base on which to build, but education cannot provide a garment of facts and techniques in which the graduate goes forth cloaked as a leader. Although the standards established for admission do not lead to a large undergraduate body, there has been a fairly steady growth of applicants.

Because of its flexibility, the course may be used, as far as the senior year, in an alternate position with other courses not only in public health but also in premedical and other fields.

Course Requirements

The usual course for the person who has selected pre-administration in his junior year includes some 44 units of selected work in the following areas: advanced psychology (usually human relations), cultural anthropology, principles of organization and management, personnel administration, managerial accounting, industrial relations, advanced economics, biostatistics, community health education, sanitation, introduction to health administration, medical sociology and medical background, and disease control. As this leaves the student a minimum of 14 additional units, other work may be selected to fit the needs or special interest of the student. Only three units of work are devoted specifically to the hospital. These are in the form of a survey course which is also taken by students from several other areas. The various types of institutions—voluntary and governmental, general, chronic, and mental—are presented in terms of their relationships to the community and to one another, as well as in the individual setting. A major objective of the survey course has been to portray the complex nature of the hospital as an institution, the kinds of problems which it faces, and the

many interrelationships with which it is concerned.

Preceptorships

Graduate students who have shown ability in their academic work and appear otherwise personally qualified are referred to the hospital administrators who have agreed to establish special preceptorships. In a very few cases carefully selected students from other schools, who have a reasonably equivalent pre-administration background, are also referred. Some students who have graduated in other fields take an extra year of graduate work prior to the internship to make up for deficiencies. This graduate year somewhat parallels the upper division pre-administration work, and these students have then entered the preceptorship on the same basis as the regular pre-administration graduate.

The preceptorship, or administrative internship, is not dissimilar to the well-established administrative residency required in all graduate courses in hospital administration. The main difference lies in the longer period of orientation to the hospital, its departments, and related activities, the somewhat more restricted degree of responsibility placed on the student in administrative situations, and the higher demands on the administrator in terms of teaching interest.

This year of education within the hospital is clearly reflected in seminar discussion and special study during the graduate academic year. Students with this background compare favorably with others whose experience in the field may have been much longer. They not only contribute to classes, but, on the basis of actual experience, are able to derive far more from case and discussion sessions at graduate level than is possible with students lacking an experiential background. Moreover, students with a minimum 2-year background following a bachelor's degree are able to enter the administrative residency with a fairly high level of preparation.

Results

The pre-administration program has been in existence only 7 years, and students have gradu-

ated from this program only in the last 5 years. Of 27 students taking their bachelor's degree in this area, 18 have continued with the advanced program, one of whom completed his graduate study at an eastern university. Fifteen students have now completed both the undergraduate program and the preparation requirement. Of that number, 8 have also completed residencies and taken appointments in the field. The rest of the 15 are either entering into residencies or the graduate academic program during the current year. Four more of the 27 graduates are now in administrative internships.

At the undergraduate level some 10 students are currently following the pre-administrative program on the Berkeley campus. Several are enrolled in a similar pre-administration program at the University of California at Los Angeles. In the past few years, a number of students who completed basically similar undergraduate programs in other schools have been placed in internships.

None of us associated with the graduate course feel that the undergraduate program outlined here is the only pattern for development of future students in administration for health fields. We do believe that the combination of social sciences, biological sciences, the humanities, and business administration, together with some background knowledge of

the health fields, is essential for a progression such as we have outlined. Such a preparatory program, however, is possible within the structure of many schools and without undue concentration by the student. Administration provides an alternate field for capable students in premedical, business administration, and several other areas. Although the field of hospital administration, itself, provides only a limited number of positions, there are at present some 200 students a year entering graduate work in this field alone, and graduates are also taking positions in allied health fields.

Careful selection and guidance of college students with real aptitude and ability can, we believe, help to attract outstanding students to the fields of health administration. Our experience with the progress of students, even though the program is still relatively new, has been encouraging to us and has proved acceptable to students, preceptors, and faculty alike.

Project to Combat Tuberculosis in Indians

A 3-year program to reduce tuberculosis among southwestern Indians will be conducted by the Phipps Institute of the University of Pennsylvania under contract with the Public Health Service.

The tuberculosis incidence is about nine times higher among Indians than among the non-Indian population of the United States. The institute will conduct field studies and administer drugs to assist in the prevention and treatment of the disease in about 8,700 children.

Affected by the plan will be the United Pueblos and the Jicarilla and Mescalero Apaches of New Mexico and the Consolidated Utes of Colorado. If techniques prove successful, they will be extended to other areas.

Poliomyelitis Survey in Rio de Janeiro

By MAURICIO MARTINS da SILVA, M.D., and JEROME T. SYVERTON, M.D.

CLINICALLY recognizable poliomyelitis was accepted in Brazil as an endemic disease of sporadic occurrence until 1953. Rio de Janeiro with a population of 2,626,875 had 25 reported cases per year from 1949 to 1952, an attack rate of 0.9 per 100,000 and a case-fatality rate of 20 percent (1). The disease occurred evenly throughout the year with perhaps a slight increase in incidence during the summer months of November, December, and January.

In 1953, the impact of a severe epidemic alerted physicians and health authorities. A total of 746 cases were reported from Rio de Janeiro. Of these patients, 561 were classified as residents and 185 as nonresidents. The nonresidents were patients from neighboring states who came to Rio de Janeiro for medical treatment. The result for this single year was a

resident attack rate of 21.5 per 100,000 and a case-fatality rate of 4.6 percent.

In 1954, the disease again assumed epidemic proportions with a recorded total of 356 patients (245 residents and 111 nonresidents). The resident attack rate was 9.3 per 100,000 and the case-fatality rate, 4.2 percent. The epidemic curves for the 2 years are shown in the figure. The analysis of the 1954 data showed that 91.8 percent of the cases occurred in children under 5 years old (83.6 percent under 3 years) and no cases were seen in persons over 40 years of age. It further showed that a larger percentage of cases (60 to 70 percent) came from higher than average socioeconomic groups as determined by the type of residency, sanitary installations, and race (67.7 percent white, 32.3 percent non-white).

Prior to 1953, the only other recent epidemic of poliomyelitis in Rio de Janeiro was in 1939. Then 287 cases were recorded.

In other tropical and subtropical countries and in areas of the world where standards of hygiene are generally poor, exposure to the poliomyelitis viruses and the consequent development of antibodies occur almost universally and at an earlier age than in communities in which hygienic standards are higher (2-9). Crowded conditions and frequent pollution of the environment facilitate the spread of any disease in which the etiological agent is present in the oropharynx and stools (8).

Serologic evidence of the extent of poliomyelitis infection in the general population of Brazil is limited to a single study reported in 1937 by Hudson and Lennette (10). These workers examined serum samples from 10

Dr. Martins da Silva, currently on leave as head of the third pediatric service, Sao Zacharias Hospital of Rio de Janeiro, is research associate in the department of bacteriology and immunology and assistant professor of pediatrics, University of Minnesota. Dr. Syvertson is professor and head of the department and consultant to the Surgeon General of the Public Health Service (Microbiology Study Section). This study was aided by a grant from the National Foundation for Infantile Paralysis.

Dr. Waldir Cordeiro de Moraes and Dr. Helio Lopes da Costa, members of the staff of the third pediatric service, Sao Zacharias Hospital, obtained the samples, and Companhia Harkson Industria Comercio Kibon and Pan American World Airways provided air transportation of these samples.

Poliomyelitis incidence by month in Rio de Janeiro, Brazil, 1953-54

Courtesy of Dr. Aristides Paes de Almeida, epidemiology service, Department of Hygiene, Rio de Janeiro, D. F., Brazil.

Brazilians ranging in age from 10 to 30 years. They resided in the town of Formosa in the State of Bahia, Brazil. The method for assay of neutralizing poliomyelitis antibodies was qualitative by present-day standards; the MV strain of virus (11) used in the study presumably was poliomyelitis virus, type 2 (Lansing). This study revealed that 8 out of the 10 persons had neutralizing antibodies for MV virus. In 1937, epidemics of poliomyelitis were not known in Bahia, and only a few deaths were reported from scattered parts of Brazil.

This study was undertaken to learn from serologic evidence the extent of previous poliomyelitis infections in Rio de Janeiro and thereby provide information helpful to an understanding of the recent epidemic outbreaks in Brazil and of the global epidemiology of poliomyelitis.

Materials and Methods

Blood samples from 111 persons of 3 representative socioeconomic groups in Rio de Janeiro and its environs were collected in July and August 1954. An attempt was made to obtain donors, aged 6 or 7 years, for a comparative study of antibody patterns in a similar age group in the United States. In group A

two-thirds of the children resided in slum areas located on the hills of the city and one-third were from a semirural grade school of the Federal District. Overcrowding, lack of minimal sanitary facilities (no sewage disposal or running water) characterized the environment of group A. Group B children were city dwellers living in small houses or apartments where sanitary and hygienic standards, as determined by running water, sewage disposal, adequate income, and no overcrowding, were greatly superior to those of the previous group. Group C included children from the upper income brackets, both Brazilian and foreign residents. Their standards of hygiene were as high as those of the Americans in groups D and E (12), consisting of children of University of Minnesota faculty members and University of Minnesota medical students, respectively (authors' unpublished experiments).

The sample of blood (about 10 ml.) was withdrawn aseptically without anticoagulant. Serum was separated from the clot within 24 hours and kept sealed in glass vials at refrigerating temperatures (2° to 10° C.). Quantitative assay for neutralizing antibodies in the serums was effected through use of HeLa cell cultures by the procedures employed routinely in this laboratory (14). This strain of HeLa cells has been maintained in continuous culture on glass in the laboratory since May 31, 1951.

Table 1. Distribution by immunotype and titer of poliomyelitis antibodies among three different socioeconomic groups in Brazil

Serum titer	Type 1			Type 2			Type 3		
	A	B	C	A	B	C	A	B	C
4,096 or more	1	1	0	3	5	1	0	2	3

C=High socioeconomic group, urban.

D=Children of University of Minnesota faculty members (5-10 years).

E=University of Minnesota medical students.

Serums were inactivated for 30 minutes at 56° C. and diluted in BSS (Hanks' balanced salt solution) medium with antibiotics and a fungicide to give fourfold dilutions ranging from 1:4 to 1:4096 (6 tubes/serum/type). One hundred TCID₅₀ (tissue culture infectious dose) of poliomyelitis virus, type 1 (Mahoney), type 2 (MEF-1) and type 3 (Saukett), respectively, were added to each serum dilution, kept for 30 to 60 minutes at room temperature, transferred to HeLa cell cultures, and incubated at 36° C. The end point of each titration was determined by microscopic observations on the fourth and seventh days as revealed by the tube with the last serum dilution completely protecting the cells from the cytopathic effect of the virus.

Results

Quantitative assay of 111 Brazilian serum samples for antibodies to poliomyelitis viruses by use of the HeLa cell tissue culture technique (13, 14) revealed for each of three socioeconomic groups comparable composite antibody spectrums as determined by occurrence and titer of antibodies (table 1). These data, by presenting the percentage distribution by socioeconomic groups of the occurrence of antibodies to each of the poliomyelitis viruses, types 1, 2, and 3, are brought out more clearly in table 2. Antibodies to all three types were found for 79 percent in group A, 53 percent in group B, and 29

percent in group C. Antibodies to at least one immunotype were demonstrated for all children in group A (average age 8 years), for 97 percent in group B (average age 11 years), and for 96 percent in group C (average age 18 years). The data provided from comparable studies of children (average age 6.5 years) of faculty members at the University of Minnesota (group D) and of University of Minnesota medical students in an age range of from 20 to 30 years (group E) were 15 percent and 16 percent, respectively. Conversely, data for the last two groups gave no evidence of poliomyelitis antibodies, (a) for 30 percent of the children less than 10 years of age, and (b) for 20 percent of the medical students from 20 to 30 years of age. These results from studies of subjects in Minnesota contrast with the results from the Brazilian population in which individuals less than 18 years of age, by socioeconomic group, range from 4 percent to none without antibody.

Discussion

The present observations establish the fact that poliomyelitis infection has been widespread in Rio de Janeiro and, presumably, in Brazil. Evidence was obtained of infection of most members of three widely different socioeconomic groups by at least 1 of the 3 antigenically recognized types of poliomyelitis virus. The percentage distribution of antibodies ranged from 96 to 100 percent. Indication of infection by all three types of poliomyelitis virus was found to vary from 29 to 79 percent in the three groups. The incidence and distribution of poliomyelitis antibodies in these three groups are similar to other areas of the world (9) with comparable sanitary, climatic, and hygienic conditions. On the other hand, a similar antibody survey for two age groups from Minnesota showed no antibodies in 30 percent of group D (average age 6.5 years) and 21 percent of group E (20 to 30 years of age). Antibodies to the three types of poliomyelitis virus were found to be 15 and 16 percent, respectively.

This serologic study shows that poliomyelitis infections have been widely disseminated in Rio de Janeiro. Presumably, the relative absence of poliomyelitis epidemics in Brazil can be explained in part by exposure to the viruses in

infancy at a time when children are under the protection of maternal antibodies.

Summary

Clinically recognizable poliomyelitis was accepted in Brazil as an endemic disease of sporadic occurrence until 1953. The disease in 1953 and 1954 assumed epidemic proportions. To provide information helpful to an understanding of the recent epidemic outbreaks in Brazil and of the global epidemiology of poliomyelitis, serologic evidence of the extent of previous poliomyelitis infections in Rio de Janeiro was obtained. Quantitative assay of poliomyelitis neutralizing antibodies in a sample of 111 serum specimens from three different socioeconomic groups (A, B, C) in Brazil was effected by using the HeLa cell tissue culture technique. For comparison, a group of University of Minnesota students (group E) and children of faculty members (group D) were studied. The common presence of antibodies to the three types of poliomyelitis viruses in the lowest socioeconomic section of the Brazilian population (group A) by the eighth year led to the conclusion that, presumably, the relative absence of poliomyelitis epidemics in Brazil can be explained in part by exposure to the viruses in infancy at a time when children are under the protection of maternal antibodies.

Analysis of the cancer nursing service in the Nassau County (N. Y.) Department of Health suggests criteria that may be useful to other health departments in appraising a cancer nursing program or as goals to strive for in such a program.

Appraising Cancer Nursing Services

—A Study to Establish Criteria—

By E. DOROTHY GORDON, R.N., B.S., VINCENT H. HANDY, M.D., M.P.H.,
FRANCES TITUS, R.N., and EARLE G. BROWN, M.D.

CANCER as a disease has long been known to mankind. Only comparatively recently, however, has cancer been generally recognized as a public health problem. In New York State, as in the Nation, cancer now ranks second only to heart disease as a cause of death. In 1953, cancer had an incidence of 281.3 reported cases per 100,000 population and a death rate of 170.4 per 100,000 population in New York State, exclusive of New York City. In view of the size and seriousness of this public health problem, the New York State Department of Health's bureau of cancer control has consistently encouraged local departments of health to develop progressive, integrated programs of cancer control, including public health nursing services.

Nursing has always had a significant contribution to make to the care of patients with

cancer, and public health nursing is peculiarly fitted to play an important role in modern-day cancer control. Public health nursing services can be expected to assume an even greater importance in cancer control programs as public health agencies give increasing attention to all the chronic diseases.

If local health departments are to develop cancer nursing services in an orderly manner, periodic, systematic appraisal of the programs is necessary. For such an appraisal, some criteria by which the programs can be measured to indicate achievements and uncover areas for further development would seem to be required. Therefore, during 1952 and 1953, the New York State Health Department's bureau of cancer control and the Nassau County (N. Y.) Department of Health undertook a study aimed at establishing criteria that could be used in appraising cancer nursing services.

The approach to the problem consisted in an attempt to find out what the essential elements of cancer nursing are as carried out in a specific area, with reference to the following questions:

1. What type of cancer patient is receiving home nursing care?
2. What is the extent of nursing care being given to the patient?
3. Can this information suggest criteria for appraising a cancer nursing program?

Miss Gordon and Dr. Handy are with the bureau of cancer control, New York State Department of Health, Albany. They are, respectively, consultant nurse and assistant director. Miss Titus is assistant director of public health nursing, Nassau County Department of Health, Garden City, N. Y., and Dr. Brown is the Nassau County commissioner of health.

Study Methods

Nassau County was selected as the area for study for several well-defined reasons.

First, it has an active, well-organized health department.

Second, the health unit has not only an active caseload of nursing visits to cancer patients, but also a sufficient number of patients and visits for valid conclusions to be drawn.

Third, its nursing records are reasonably complete and are readily available for study.

Fourth, in addition to a public health nursing service, other community resources, including hospital, clinic, and ancillary services, are available within or close to the area for assistance in the total care and rehabilitation of cancer patients.

Finally, diagnostic reports are accessible and completely reliable. It was agreed early in the planning period of the study that only those patients for whom a diagnosis of cancer had been made and reported to the health department prior to referral for nursing service would be included. This decision eliminated study of one of the nurse's most valuable contributions to the cancer control program, that is, followup of the "suspected" case until cancer is diagnosed or ruled out. However, it was felt that for the primary purpose of this study, only diagnosed cancer patients should be included, in the interests of accuracy and reliability of the data.

In addition to meeting these general requirements, Nassau County has three specific characteristics which make it an appropriate locale for the study.

First, there is sustained professional and public interest in cancer, as shown by the formation in 1928 of the Nassau County Cancer Committee, and later the appointment of a health educator to its staff, and by the establishment of a tumor clinic in the county hospital in 1932.

Second, the public health nursing service of the Nassau County Health Department reaches a large percentage of reported cancer cases. Since its inception in 1938, the nursing service has been generalized, with each staff nurse giving service to any person in her area referred for health supervision and nursing care in the home. In 1940, it became apparent that the nurses needed more specialized knowledge of

cancer, and a comprehensive inservice education program was started. This program has been continued regularly since that date.

Third, the county health commissioner possesses a firm conviction that cancer nursing is an integral part of and a legitimate function of a comprehensive, generalized public health nursing service, and that as emphasis in public health shifts toward the chronic diseases, the same trend should occur in public health nursing. He and his staff have worked steadily and imaginatively to create and develop good rapport between the county health department, the county cancer committee, and local practicing physicians.

The success of the Nassau County Health Department's approach is reflected in the referrals of cancer patients to the public health nursing service. During the period July 1, 1952, to June 30, 1953, 488 new cancer patients received nursing service out of 1,599 cases in the county reported before death, a percentage of 30.5. The average for upstate New York was 14.1 percent, exclusive of patients receiving care from visiting nurse associations.

The proportion of cancer patients to the total number of patients receiving nursing services is even more interesting. During the same 12 months, the Nassau County Health Department provided nursing services for 21,833 patients. Of these, 626, 2.8 percent, were cancer patients (including both new patients and those readmitted to service). In the rest of New York State, exclusive of New York City, 737 cancer patients received nursing care from the official agencies out of 83,587 patients carried for all nursing services, a percentage of 0.8. The difference between the makeup of the nursing load in Nassau County and that of the rest of the upstate area is statistically significant.

The time period selected for the study was July 1, 1952, through September 30, 1953. One hundred thirty-six new cancer patients consecutively admitted to nursing service during the first 12 months of that period composed the study population. Some difficulty was experienced in accumulating this number of patients for study because frequently patients were referred for nursing service before a definite diagnosis was made. Only those patients for whom a definite diagnosis of cancer had been made

and reported to the health department prior to referral for nursing service were included in the study group.

The nursing service for each patient was studied for 3 months, unless the patient died or was discharged earlier. A worksheet, shown above, was devised for recording the desired data and was completed for each patient in the study. The data were obtained almost exclusively from the nurses' records; interviews with nurses for the collection or supplementation of data were kept to a minimum.

Sex Distribution and Leading Sites

The sex distribution of the patients in the study favored females. Eighty-one, 59.5 percent, were females, and 55, 40.5 percent, were males. The distribution of all reported cancer cases in Nassau County in 1953 was more nearly equal; 48.3 percent of the cases were in males, and 51.7 percent were in females. It may be that more women than men received nursing service because the site of the cancer and the special needs of patients having cancer of cer-

tain sites determine which patients are referred for nursing care.

Cancer of every system and of most anatomical sites was represented in the study group. As shown in table 1, 5 sites accounted for about 60 percent of the nursing caseload: intestine, breast, rectum-anus, respiratory system, and skin. In Nassau County in 1953, the respiratory system and the intestine were the second and third most frequent sites of cancer among males, exceeded only by the skin; and the breast was the leading site of cancer among females. In the study group, patients with cancer of the intestine and those with respiratory cancer were the most numerous among the men, and patients with breast cancer were the most numerous among the women. These data indicate that the distribution of nursing care patients by site of the cancer tends to follow the distribution of all reported cancer patients.

Physical Care Services

Of 1,290 physical care services given, the women received 935 (72.4 percent), nearly 3 times as many services as the men. As previously stated, there were only about 1½ times as many women as men in the study group. One possible explanation for the preponderance of physical care services being given to the women is that the site of the cancer dictates the amount and kind of physical nursing care necessary. The data in table 2 tend to support this view.

Cancer of the respiratory system, one of the leading sites among the men, received only 3.8

physical care services per patient. This may be because of the limits to home nursing care imposed by cancer of this site. In general, the course of lung cancer, as compared with cancer of other sites, is of relatively short duration. Much of the treatment is given in the hospital, and upon discharge the patient may have little need of physical nursing care services.

On the other hand, cancer of the breast, the leading site among the women, may require a number of physical care services, such as dressings and rehabilitation procedures, to be given

in the home. Breast cancer received 12.6 physical care services per patient, next to the highest number of services given to the women.

Considering all women patients and all men patients, however, we find that the women required an average of 11.5 physical care services as compared with 6.4 for the men. Possibly the reason for this difference lies in factors not revealed by the data collected for this study.

Table 3 shows that 5 types of service accounted for 93 percent of all physical care services given: general care, dressings, irrigations, injections, and enemas. For the men, general care was given most often; for the women, irrigations were most common. It should be noted here that one elderly woman in the group received an unusually large number of irrigations given by the nurse because it was not possible for a member of the family to assume complete responsibility. In this relatively small group studied over such a short period of time as 3 months, it is possible that 1 or 2 patients may influence the statistical picture to a disproportionate degree.

Supportive Care Services

It is difficult to make a division between physical care services and supportive care services in evaluating total nursing services. For the purpose of collecting and analyzing the data, an attempt was made in this study to make such a division, but for interpreting the data it is necessary to bear in mind certain intangible factors that operate significantly in good nursing care. For example, it is hard to imagine a good nursing visit made for the purpose of

Table 4. Distribution of supportive care services according to site of cancer

giving a bath or doing a dressing that does not also include some awareness by the nurse of the patient as a person, with his emotional needs and responses peculiar to himself at that time.

Of 357 supportive care services given, women received 223 (62.5 percent), and men, 134 (37.5 percent). This follows fairly closely the sex distribution of the study group.

Table 4 shows that there was little difference between the sexes when the distribution of supportive care services by site was studied. The men averaged 2.4 supportive care services; the women, 2.7. As with physical care services, the number of supportive care services per pa-

¹ Includes motivation to medical care, referral to other agencies, followup nursing supervision, and other services.

tient tended to be more affected by site of the cancer than by sex of the patient. Cancer of the intestine, for example, required the most supportive care, regardless of the sex of the patient.

According to tables 2 and 4, approximately 3½ times as much nursing service was devoted to the physical care of the patient as to his supportive care. As previously noted, however, it is next to impossible to divorce physical care from supportive care. It is very probable, therefore, that more supportive care was given than would be indicated by the nurses' records. Good nursing care includes recognizing and attempting to meet the emotional needs of the patient as well as the physical needs. But so much of supportive care is incidental, if not

perhaps unconscious, that nurses usually do not record it. This is unfortunate since the public health nurse is especially trained to assist in those services listed as supportive. Unless it is clearly understood and accepted that this service is an important and integral part of her function, many persons may be led to assume that physical care services alone constitute an adequate nursing visit and that the visit can thus be made by someone with less formal training. For the maximum service to the patient, complete nursing care must include both physical and supportive care to the degree indicated by the needs of the patient.

The most interesting finding revealed by table 5 is that three general types of supportive service—emotional support, general health instruction, and assistance with special problems—comprised approximately 80 percent of all supportive services. Furthermore, with minor deviations, these three types were about equally distributed among men and women.

Extent of Nursing Care

One measure of the extent of nursing care was obtained by tabulating physical care services according to three classifications as shown in table 6: services given by the nurse, which included care given to the patient in which demonstration or teaching was incidental rather than a primary objective; services demonstrated to the patient or family, which included care given by the nurse to show how to do a procedure, the eventual goal being to have the patient or his family assume this responsibility; and services supervised, which included the nurse's visit to observe a procedure, answer

questions, and evaluate the situation after the patient or family had assumed responsibility for care.

A large percentage of the physical care services were actually administered by the nurse, and only a small percentage were demonstrated to the patient or family. Although this was true for both men and women, a higher percentage of services were demonstrated for the men than for the women. One explanation for this difference might be that a wife is more likely to assume nursing duties when her husband is ill than is a husband when his wife is ill. It was also found that a large proportion of the study group were in the late stage of the disease. Nearly a third of the patients died within 3 months after admission to nursing service. It can probably be assumed that a great many of the patients were already too ill and the family already too exhausted physically and emotionally for anyone but the professional nurse to undertake the patient's care.

"Services supervised" should be one indication of the patient's or family's degree of success in achieving self-sufficiency. The nurse was satisfied that self-sufficiency had been attained in 8.5 percent of the physical care services for men and in 5.1 percent for women.

Table 6 also shows a tabulation of supportive care services according to services directed to the patient and services directed to the family. More of the services fell into the first category than the second for both men and women. This finding may be a demonstration of a desirable principle of nursing care, that is, help the pa-

tient to help himself first and thus aid him in establishing independence and security.

The women patients received a higher percentage of supportive care services directed to themselves (69.9 percent) than did the men (56.7 percent). It may be that in many instances other members of the family were at places of employment outside the home at the time of the nurse's visit. However, it was the exceptional patient who lived alone.

Age, Referrals, and Disposition

The men in the study group tended to be older than the women, with 92.8 percent of the men over 45 years of age compared with 77.8 percent of the women. However, the number of visits per patient was higher in each age group for women than for men. The greatest number of visits per patient occurred in the 25-34 age group for women, but there were very few patients in this group. The data on age and number of visits are shown in table 7.

As shown in table 8, 88 patients (65 percent) were visited by the public health nurse on the day of referral, and 104 (76.4 percent), within 2 days. Seventeen patients (12.5 percent) were not visited until the ninth day or later. A local situation in the county may have some bearing on this last finding. Fourteen of these seventeen patients were referred by the local hospital, which has a tumor clinic. All patients attending the clinic are referred to the health department nursing service for followup or because of missed clinic appointments. The

Table 7. Age distribution of patients and number of nursing visits

Total.....	88	16	15	17	136	100.0

patient's clinic return date may be a considerable time after the date referral to the nursing service is made, and these referrals receive no priority in the public health nurse's schedule. Therefore, the nurse may delay her first visit until near the time of the patient's clinic appointment. If immediate nursing were needed, the referral notice would so indicate. With the exception of these 17 patients, the time interval between referral and first nursing visit was fairly consistent for the various sources of referral.

Table 8 also gives the number and percentage of patients referred by each source. Of the 72 patients (nearly 53 percent) referred by private physicians, 46 were women and 26 were men, a male to female ratio slightly more in favor of women than the sex distribution of the study group. Of the 50 patients (36 percent) referred by the hospital, women numbered 26, and men, 24. Other sources, which accounted for only 14 of the patients, included self or family.

A striking fact revealed in table 9 is that, of the 135 patients for whom the stage of disease was known, 121 (89.7 percent) were in the late stage when diagnosed. Only 14 (10.3 percent) were in the early stage. In 1953, Nassau County reported 1,900 new cancer cases. The physician designated the stage of disease at time of diagnosis in 1,603 of these. Of this group, 334 (20.8 percent) were cases in the early stage of disease.

The fact that a preponderance of the cases referred for nursing service were late cases may have significant implications for nursing. If we believe nursing as well as medicine can make its maximum contribution to the welfare of the patient during the early stage of a disease,

then obviously the opportunity diminishes as the disease progresses. But physicians may feel that the patient should be maintained without nursing supervision in the home until the late or even terminal stage has been reached. Table 9 shows that 42 patients (30.9 percent) died within 3 months after referral (the period of study of each patient), a finding that appears to lend support to this theory. Possibly physicians do not wish some patients to know or even suspect the diagnosis of cancer and feel that referral for nursing care early in the course of the disease might arouse the patient's anxieties. Or perhaps patients are referred for health department nursing care only after the family has exhausted its own resources, both physical and emotional.

Table 9 also reveals that 37 patients, 27.2 percent, were discharged to themselves or their families. It may be inferred that these patients had achieved enough self-sufficiency to be responsible for their own followup, subject,

¹ Stage of disease unknown for one patient.

of course, to regular medical supervision. If those patients who died are excluded from the calculations, then the percentage of patients who achieved self-sufficiency is 39.4. This finding is especially gratifying since 89.7 percent of the patients were already in an advanced stage of the disease when referred for nursing service. Forty-one patients, 30.2 percent, were still receiving visits at the end of the 3-month period of study.

Criteria and Goals

From this study and from the Nassau County Health Department's experience emerge certain findings which we believe may be useful to health officers as criteria for evaluating a cancer nursing service or as goals to strive for in such a program, even though the study group was small and the study period short. These findings have been divided into two groups: group A, those that may be reproducible elsewhere, that is, those that should not be influenced by local conditions; and group B, those that may be peculiar to this county because of local circumstances but that we feel indicate a good quality of service and are therefore desirable in a well-integrated cancer nursing program.

GROUP A

1. At least 30 percent of the reported cancer cases, exclusive of those reported at time of death, are receiving public health nursing service.

2. At least 2 percent of the total patients carried for public health nursing are cancer patients.

3. The distribution of cancer patients referred for nursing service, both male and female, corresponds to the distribution of the predominating cancer sites of all patients in the locality.

4. The site of the cancer, rather than the sex of the patient, largely determines the number of physical care services and supportive care services given.

5. Physical care services constitute an important part of the cancer nursing visit. They con-

sist predominantly of general care, dressings, and irrigations.

6. Supportive care services also constitute an important part of the cancer nursing visit. They consist predominantly of emotional support and general health instruction.

7. One measure of the effectiveness of the nursing service is the proportion of patients discharged either to themselves or their family.

GROUP B

1. In a health department where there is effective cancer reporting and an established nursing service and where there is a genuine desire to provide nursing services for chronic disease patients, 30.5 percent of the reported cancer cases, exclusive of those reported at time of death, are receiving nursing care. This cancer caseload constitutes 2.8 percent of all cases carried for nursing service.

2. The public health nurse visits 76 percent of the referred cancer cases within the first 2 days.

3. Referrals for nursing service present the following pattern: 53 percent by private physician; 37 percent by hospitals; 10 percent by self, family, or other community agency.

4. Twenty-seven percent of the patients are discharged either to themselves or their family within 3 months after the nurse's initial visit. When those patients who die are excluded from this calculation, 39.4 percent of the cases achieve this measure of self-sufficiency.

5. The average number of visits per cancer patient ranges between 7 and 12, depending on age and sex of the patient.

It is not realistic, of course, to expect other health departments to arrive at exactly the same results in appraising their cancer nursing programs as were found in Nassau County. But the health officer may find these criteria and goals helpful in reviewing his cancer nursing program. In the course of such an appraisal, he should honestly ask himself what factors are governing his cancer nursing service. Is it a token service to satisfy community pressures? Is it dependent upon the interest of only a few nurses? Or is it a planned program within the framework of his public health objectives?

idea

Modified Oscilloscope

Monitoring a patient's blood pressure and electrocardiogram in difficult heart surgery has vital significance to the surgeon and anesthesiologist. The usual monitoring device is a cathode-ray oscilloscope. These oscilloscopes are expensive, often bulky, and because of an excessive number of controls, rather difficult to operate.

These disadvantages have recently been reduced by a modification of this instrument by F. W. Noble, M.E.E., B. R. Boone, M.D., N. McC. Garrahan, and R. E. Gorman of the National Heart Institute, National Institutes of Health, Public Health Service.

The National Heart Institute announced the successful application to an electrocardiograph machine of a version of an electronic switch that makes possible the adaptation of all existing single-beam oscilloscopes to perform like more complex double-beam instruments.

Though the cheaper and more frequently available single-beam oscilloscope has only one light source, with the addition of the electronic switch, it traces two curves on the screen. This is achieved by a rapid redirection and alternation of the light source between the curve above and the curve below. The switching process continues indefinitely, leaving behind two separate and distinct tracings.

A detailed technical description of the switch appears in the September 1955 issue of *The Journal of Laboratory and Clinical Medicine*.

Malaria Control in Turkey

By FREDERICK W. KRATZ, M.D., and
C. BRADLEY BRIDGES, M.P.H.

TURKEY—astride the strategic Bosphorus and Dardanelles—has long been a land of mystery and enchantment to the average American. Its civilization is what one would expect of a country which lies partly in Europe and partly in Asia. Though turned toward the West in thought and ideas, it is a nation blending the customs of Eastern and Western cultures in spite of the prediction that “ne’er the twain shall meet.”

Asia Minor, or Asiatic Turkey, is about 97 percent of the total land area of the country (287,246 square miles). Thrace, the extension of the European Balkan Peninsula, occupies only about 3 percent. Both portions of the once great Ottoman Empire are historically malarious. The Sultan’s soldiers, returning from World War I to rally around Kemal Ataturk, not only maintained malaria in epidemic proportions but brought with them strains of new plasmodia, which swept through the homeland with renewed energy (1, 2).

In the years since the founding of the Repub-

lic of Turkey, in 1923, great emphasis has been given to improvement of the general health. Malaria incidence has been in general decline since 1946 as a result of the persistent control operations under the Directorate of Malaria Control (3). These efforts had long been hampered by general shortages of funds, equipment, and insecticides.

In May 1950 the United States Economic Cooperation Administration Health Mission to Greece sent representatives to Turkey in order to establish the basic agreements which led eventually to a program of material and technical assistance in malaria control.

In November of the same year a working agreement was set up between the Economic Cooperation Administration and the Turkish Ministry of Health and Social Assistance. The ECA public health group, composed of a physician, sanitary engineer, and malariologist, arrived in Ankara in March 1951 to work as consultants in the malaria control operations of the Turkish Ministry of Health until the close of the assistance program, June 30, 1953.

Material assistance furnished under these agreements included principally insecticides, sprayers, and automotive equipment.

Dr. Kratz and Mr. Bridges went to Turkey in 1951 as public health consultants. Dr. Kratz, who is medical officer in charge, Pacific Northwest Foreign Quarantine District, Public Health Service, Seattle, was chief of the public health group during the malaria control program. Mr. Bridges was the malariologist with the group and is now training officer at the Communicable Disease Center, Public Health Service, Atlanta. The third member of the group was George W. Hintgen, malaria control engineer.

Progress in International Cooperation

¹ Turkey has four separate topographical regions whose climates are completely different. Each region presents its problems in the control of malaria.

Asiatic Turkey is almost completely ringed with mountains which fall away rapidly toward

Modified Oscilloscope

Monitoring a patient's blood pressure and electrocardiogram in difficult heart surgery has vital significance to the surgeon and anesthesiologist. The usual monitoring device is a cathode-ray oscilloscope. These oscilloscopes are expensive, often bulky, and because of an excessive number of controls, rather difficult to operate.

These disadvantages have recently been reduced by a modification of this instrument by F. W. Noble, M.E.E., B. R. Boone, M.D., N. McC. Garrahan, and R. E. Gorman of the National Heart Institute, National Institutes of Health, Public Health Service.

The National Heart Institute announced the successful application to an electrocardiograph machine of a version of an electronic switch that makes possible the adaptation of all existing single-beam oscilloscopes to perform like more complex double-beam instruments.

Though the cheaper and more frequently available single-beam oscilloscope has only one light source, with the addition of the electronic switch, it traces two curves on the screen. This is achieved by a rapid redirection and alternation of the light source between the curve above and the curve below. The switching process continues indefinitely, leaving behind two separate and distinct tracings.

A detailed technical description of the switch appears in the September 1955 issue of *The Journal of Laboratory and Clinical Medicine*.

Studying the biology of vectors.

years activity patterns have evolved which substantially increase the opportunity of malaria transmission in the presence of capable vectors.

The sparse summer rainfall in most of Turkey necessitates the extensive use of irrigation during the growing season. The improper management of irrigation water in rice culture and in other crops leads to a malaria problem here as well as elsewhere in the world.

The danger from rice irrigation is somewhat reduced by a law which requires that all rice fields less than 3 kilometers from a village be dried 48 hours every 10 days, but there is no such control on water used in irrigation of other crops to lessen mosquito breeding (4).

The lack of fences in Turkey has led to the custom of crop watching. During fruiting time a watch is maintained from an elevated platform day and night against marauding men and livestock. The guard is often joined by his entire family. With a most convenient blood meal near at hand, the vectors need not travel to the villages or herds to fill their needs. A similar blood-feeding situation results when the people sleep on rooftops to escape the inside heat on hot summer nights.

As in the United States, laborers migrate from one area to another during the harvest season. They live in tents or other temporary dwellings impossible to cover in a control program, then return when the harvest season is over to their Anatolian homes, carrying infec-

tions with them. Migrations of a lesser magnitude are those of a few nomadic tribes who follow grazing as the seasons open or close.

The Malaria Control Organization

Owing to the prevalence of malaria in Turkey in the period following World War I and the early days of the Republic (5), malaria control activities were begun on a national level by the Ministry of Health and Social Assistance in 1925.

Studies of the mosquito fauna in those years established the presence of such formidable vectors as *Anopheles superpictus* as well as *Anopheles sacharovi*. Although the existence of three subspecies of *Anopheles maculipennis* was also established, these subspecies (*typicus*, *messeae*, and *melanoon*) were fortunately not the efficient vectors of southern Europe (6). Seven other *Anopheles* were established, namely, *algeriensis*, *claviger*, *marteri*, *multicolor*, *plumbeus*, *sergentii*, and *hyrcanus* (7).

The malaria workers of the Directorate of Hygiene enjoyed reasonable progress until the World War II period. Economic crises and shortages brought widespread epidemics to the Mediterranean and Aegean areas. In 1946 malaria control was set up as a separate division for the administration of the program. The National Assembly gave legal authority to the new agency to control malaria by almost any effective means (4).

Operating at a high federal level, the directorate, under the Ministry of Health and Social Assistance, carried out its program through

Examining patient for spleen enlargement.

the sea, forming a strip of flat coastal plain of varying width. This plain is adjacent to the Black, Marmara, Aegean, and Mediterranean Seas. European Turkey is also a coastal plain since it is the corresponding area between the Balkans and the Black, Marmara, and Aegean shores.

Malaria has been firmly entrenched in the coastal plain for centuries. This is particularly true of the Aegean and Mediterranean areas where Greek and Roman cities suffered the ravages of the disease. Its ample rainfall and mild-to-tropical climate make it still the area requiring most attention.

The watershed from the coastal side of the mountains, the flood plains of great rivers entering the sea, and the outcropping of the water table furnish ample mosquito-breeding habitats in the form of pools, marshes, and seepage areas. In the south the mosquito-breeding season is continuous, with only minor recessions in winter. Progressing northward, more definite seasonal lines may be drawn.

More than half the land area of Turkey is in Anatolia, a high, saucer-shaped plateau, much like the arid plateaus just east of the Rocky Mountains in the United States. Anatolia, the Turkish homeland, may be called the heart as well as the breadbasket of the country.

The winters are cold and the summers are hot with cool, breezy nights. Continuous warm weather does not begin until very late spring, confining mosquito breeding generally to the months from June to October. Dry summers limit malaria transmission to areas adjacent to water courses or to the numerous brackish marshes and lakes. Villages are, of necessity, located near water sources, thereby making malaria control services obligatory in most areas of Anatolia. The necessity of irrigation is general. However, the annual grain crop is largely dependent on the heavy snow and rain of winter.

Since large parts of Anatolia are not drained by the big river systems, runoff water often accumulates in large marshes and lakes. This makes wasteland of vast areas. Spring floods expand their size enormously, and summer drought greatly reduces them, leaving crusty layers of mineral salts after the water evaporates.

The rugged mountain country of eastern Anatolia has narrow, fertile valleys where good crops of grain and fruit are grown. The severe winters, short summers, and restricted breeding areas place natural limitations on malaria. Southeast Anatolia is a foothill region where the mountains decline to the rolling hills of Syria, Iraq, and Iran. Primitive living conditions plus long, hot, dry summers, which are relieved by heavy autumn, winter, and spring rains, make malaria control measures necessary. Some of the highest spleen rates are reported from southeast Anatolia.

Prior to the arrival of Osmanli, or Ottoman Turks, in the 11th century A. D., the residual population of Asia Minor was subjected to the sweeping tides of conquests from both the East and the West. Almost any racial characteristic can be found from the Mongoloid to the Nordic, but the people are predominantly of the Mediterranean type. The highest population densities are found in the approaches to Europe, that is, the Marmara and Black Sea coastal plains. Not only are many of the larger cities located there, but the towns and villages are larger and more numerous.

Turkey is predominantly a rural nation. Only 7 percent of its population lives in the urban centers above 50,000 in population. The term "rural" as applicable to the United States cannot be used here. Isolated homesteads are nonexistent. The entire population lives in communal groups from small villages to larger towns and cities. In the United States we speak of malaria as being a rural problem, but in Turkey it is a village problem.

Malaria has no doubt played a leading role in shifting greater densities to the Marmara and Black Sea coasts. Along the Aegean there have been Roman and Greek cities of fabulous size and grandeur—Troy, Ephesus, Perga, Aspendus, Soli, and Korykos. They are ruins today, mute evidence of the combined influence of malaria, decadence, and earthquakes. Even in recent years, Antalya, the modern counterpart of Perga, has reported malaria rates as high as 85 percent (1).

A large majority of the people are engaged in various agricultural pursuits, which include herding livestock as well as intensive cultivation of small vegetable farms. Through the

Table 2. Percent of total hospital admissions and deaths among malaria admissions, 1946-51

Year	Percent of admissions	Percent of deaths
1946	5.0	2.6
1947	3.6	2.4
1948	3.2	2.0
1949	2.7	1.6
1950	1.6	1.4
1951	1.4	1.1

Table 3. Progress in reduction of malaria incidence, 1946-52

Year	Spleen index	Percent reduction
1946	25.9	
1947	19.8	24
1948	14.7	26
1949	10.5	28
1950	7.1	30
1951	4.3	54
1952	2.1	40

were confined to persons having highly indicative clinical symptoms. Presently these surveys cover:

Spleen examinations for all inhabitants of village included under malaria control.

Blood smears on all children up to 10 years of age.

Blood smears on all persons having positive spleens.

Owing to the fact that the results of blood and spleen surveys through the years cannot be correlated, only the results of the spleen examinations have been tabulated. Blood examinations were done for the past 5 years, and spleen surveys were carried on for 27 years. Tables 1-3 cover only the results of village or rural examinations. There are clinics in the cities and large towns where people seeking medical treatment are examined. Should these reports be included, the population protected would be more than 9 million, or nearly half the total population.

Since some 80 percent of the malaria reported in Turkey is caused by *Plasmodium vivax* (1), Turkish physicians are accustomed to have between 20 percent and 30 percent of their treated

patients relapse under the present system of therapy. Any new drug on the market that can reduce this relapse rate is looked upon with great anticipation. The efficacy of primaquin with chloroquin has been covered in numerous training courses and conferences. The adoption of the use of more effective antimalarials is further hindered by the fact that a large stock of atabrine was brought from Egypt in 1951.

Vector Control

The success of any control measure in Turkey is dependent on how well the measure ties in with the habits of *A. sacharovi* and *A. superpictus*. Although there are anopheline vectors (*A. claviger*, *A. bifurcatus*, and *A. sergentii*) present which are of importance in other areas, in Turkey they are of secondary importance. Village houses are used to shelter animals as well as humans. Readily available animals for blood meals doubtless form protective barriers around man which are penetrated mainly by those primary vectors (*A. sacharovi* and *A. superpictus*) which show a definite preference for human blood.

Several of these anophelines have characteristics so similar that the species are separated only with difficulty. Identification involved time and equipment out of proportion to our systems. A primary accomplishment of the period of United States cooperation was the development of a simple pictorial key by which species could be separated in the field with a hand lens.

A program of routinely collecting larvae and adult mosquitoes was introduced also. Morbidity records have existed for some time. By correlating records of morbidity and vector indexes, justification for control operations can be established.

Since limited amounts of DDT were available for malaria control in the past, considerable emphasis was placed on oil larviciding of breeding areas. DDT first became available to Turkey in 1946, beginning with 2 tons, and gradually increasing to almost 100 tons in 1949. As more DDT became available from United States aid (750 tons a year for the next 3 years), larvicides were deemphasized, and DDT residual spraying assumed a more important role.

provincial and district medical directors at the local area. This same type of organization is still in existence. With the advent of United States cooperation, new areas were included in the control program.

The sanitarian is the key man at the local level. Though subprofessional by training and experience, he is responsible for substandard diagnostic screening of malaria cases, the dispensing of antimalarial drugs, entomologic inspections, the supervision of residual spraying and larviciding, and the gathering of statistical data. He is directly responsible to a medical officer, who either substantiates or disproves the diagnoses made by the sanitarian. A sanitarian is assigned to 10 to 15 villages and is required to visit each village twice a month on schedule.

The Directorate of Malaria Control is administratively in control of the Malaria Institute in Adana, which is its training arm. Inservice training is generally given at three different levels.

1. Physicians are given a 6 weeks' course in all phases of malaria work from diagnosis to insecticide dispersal. On returning home, they give similar courses for their associates in the district and throughout the province.

2. Laboratory technicians are given training for a similar period in the preparation and identification of blood parasites as well as taxonomy of mosquitoes and other insects.

3. Sanitarians' inservice refresher courses usually are of 4 weeks' duration. Designed to meet the needs of sanitarians in the field, the subjects are approached from a practical point of view. Although coverage is given to all phases of malaria control activities, particular emphasis is given to insecticides, their use, and application. A formal 3-year course in all phases of sanitation activities prior to service in the various directorates is continually improving the quality of sanitarians. The supply of these graduate sanitarians does not fulfill the needs of the Ministry of Health.

At local and national levels inservice training of the older and nongraduate sanitarians is a major endeavor aimed at raising their efficiency in the broad field they cover in addition to the malaria control program.

During the period of United States assistance in malaria control, these courses were a cooperative enterprise. The Public Health Service officers were instructors at the Malaria Institute. Such joint undertakings served to improve working relations and to promote a deeper understanding of existing problems. The courses, more than anything else, served to disseminate information quickly to the operational level.

Malaria Control Operations

Examination and treatment of suspected cases of malaria have been mainstays of the operational program. During the normal season, a sanitarian on his routine visits to each village makes the diagnoses and issues anti-malarials, usually atabrine. Guided by an operational manual, he maintains records dealing with every occupant of each house in the village. Such pertinent data as splenic enlargement, results of blood examinations, and age and sex of the occupants are recorded. The examinations of blood for malaria parasites are made by the local physicians and technicians assigned to the malaria control program.

Since 1946, a malaria survey has been made each fall by the district medical director in each village of the 34 control areas. Great emphasis has been placed on enlarged spleens as an index to the prevalence of malaria. Since 1951, more emphasis has been placed on blood examinations. Before this period, blood examinations

Table 1. Data on Turkish spleen examinations, 1946-54

annual application is performed during a 6-week period in the spring. However, in the more tropical regions where there is no marked break in the mosquito-breeding season, two or more additional applications are required.

For the most part, the buildings in rural Turkey are constructed of mud and similar materials. More than 80 percent of the buildings have these porous and absorptive surfaces for which emulsions and solutions of DDT are not suited. Therefore, water-wettable suspensions of DDT have replaced these other formulations. Solutions and emulsions are used for spraying less absorptive surfaces for areas where the white residue of water-wettable DDT would be objectionable. The flat fan spray nozzles with delivery rates of 0.2 and 0.4 gallon a minute are standard equipment in all spray operations. The stainless steel tip nozzle, which is designed for delivery at 0.4 gallon a minute, has given better service with DDT suspensions than the brass tip nozzle because erosion does not enlarge the aperture so quickly.

DDT has been used in limited amounts since 1946 with no reported ill effects to humans since adequate precautions have been taken to protect food, utensils, and sprayer operators. In some provinces in 1952, DDT was believed to have contributed to a high mortality in silkworms. Silkworm culture is carried on inside homes, and spraying in the homes leads to obvious difficulties. Special instructions excluding the homes from spraying operations have thus far prevented a recurrence of damage claims.

General insect control to a high degree has

been achieved during the past three seasons with chemicals. The spray program has been popular, more often for comfort and convenience than for malaria control. People outside the 12,600 villages under control have attempted various means to have their villages included in the program.

Water-wettable DDT is mixed for spraying in a Kurd village in eastern Turkey. Note goat-skin water bags.

In Turkey, as in all other parts of the world, houseflies have developed some tolerance to DDT. Though many claims of resistance can be attributed to localized operational inadequacies, the main fault lies in the fact that housefly control is unobtainable after a few years of DDT spraying and related chemicals, when such measures are not part of an integrated sanitation program which includes proper disposal of garbage and human wastes.

The reports of resistance in *A. sacharovi* from Greece caused some concern, but where efficient spray operations prevailed there were no credible parallels observed in Turkey. Most cases investigated revealed that DDT residues had been masked by smoke, greases, and the like, or that hard-to-reach surfaces had not been sprayed.

The existence of true resistance or modified behavior patterns due to irritant repellancy of DDT (9) was not established by biological tests during the period of American aid in malaria control.

Malaria in Turkey has been reduced to a fraction of its former incidence. As in many parts of the world, the extensive and intelligent

Indicating mark of DDT application.

Mixing spray materials.

Where larviciding is indicated, it is accomplished with the use of a DDT solution made with fuel oil to which a spreading agent was added. Applications approximating 1 gallon an acre (0.1 pound DDT) in a fine mist spray are the rule.

Heavier residual larvicidal applications with DDT emulsions (3 pounds an acre) are used in selected locations on isolated ponds. Since many of these ponds dry up in midsummer, a single application will suffice for the season. These applications result in a considerable saving in the cost per acre-week over the older oil-larviciding methods.

Major drainage works are the responsibility of the Turkish Ministry of Public Works. Since the ministries coordinate their drainage projects through this agency, drainage on a large scale for malaria control alone does not occur. It is usually tied in with such projects as land reclamation, but still the benefits extend to malaria control.

Malaria control workers are trained in the fundamentals of drainage which they apply on a local level in small hand drainage proj-

ects. The effectiveness of residual spraying in controlling malaria has largely reduced drainage operations to the maintenance of existing ditches and small channels.

DDT Residual Spraying

Malaria in Turkey can be controlled by directing control activities only at the mosquitoes which play a role in the actual transmission of the disease. This principle of control by "species sanitation" requires a deeper understanding of the life history and habits of the vectors so that an attack can be made at a vulnerable point. The purpose of DDT spraying in homes is to control the vectors at the point where blood meals are taken from man, and where the accompanying transfer of parasites takes place, that is, in homes where humans are attacked during sleeping hours or other periods of inactivity.

The most important vectors in Turkey enter barns and houses in search of victims from which a blood meal may be taken. Sometime during this sojourn the anopheline will seek a quiet dark place in which to rest. This rest may come after its flight from the breeding area or after it has heavily gorged on the victim's blood. If DDT residues have been applied to every likely resting place, the infected mosquitoes are killed, breaking the chain of transmission.

DDT spraying on this basis has given protection to more than 9 million people each year since American aid was instituted in 1951. This assistance greatly increased the amounts of DDT available for more extensive coverage and made possible the inclusion of more villages in the operational area. Lack of adequate quantities of DDT previously limited spraying to selective spot applications within houses and also limited the number of houses to be sprayed in the selected villages. For the first time skilled DDT spraying became available for every house in each village.

An efficient spraying of all buildings at a dosage of 2 grams a square meter (214 milligrams a square foot) in each village in malaria control areas is being achieved. These buildings normally include stables, dwellings, mosques, shops, and village halls. The single

The United States-Iraq Cooperative Health Program

By GLENN S. USHER, M.D., M.P.H.

THE objective of the United States program of public health assistance in Iraq is to help the Iraqi Government organize modern, efficient public health services in the 14 provinces (liwas) and the major cities of the country. Although this has been the objective of the program since its inception in 1952, it was only after 2½ years had elapsed that it was formalized into a 5-year plan. To achieve the objective, it was obvious that rather large numbers of public health personnel would have to be recruited and trained. It was the result of planning for this training that the 5-year plan evolved.

Background

Iraq was formerly known to the West as Mesopotamia, which means "the land of two rivers." The country depends upon the Tigris and Euphrates Rivers for irrigation and heavy commerce.

The northern part of the country is mountainous, but in the southern part there are large marshy areas. The western part of the country forms part of the Great Arabian Desert.

Dr. Usher served as chief of the Public Health Division of the United States Operations Mission to Iraq from June 1952–October 1955. He is now chief of the Program Development Branch of the Division of International Health, Public Health Service.

Of the three main cities in the country—Basra, Baghdad, and Mosul—Basra is a port city near the Persian Gulf; Baghdad, the largest city, lies on the Tigris River in the mid-portion of the country; and Mosul is on the Tigris River in the north, away from the main lines of communication.

The climate in the central and southern areas is extremely hot in summer and mild in winter. North to Mosul and the mountains, the summer climate is less severe.

The economy of Iraq is based upon agriculture and oil resources. For the most part, agriculture is dependent upon irrigation. As a result of the slow gradient of most of the irrigated land the flow of water in irrigation ditches is sluggish. In addition, to prevent salting of the soil, drainage canals have been built to draw off the irrigation water. Such irrigation and drainage ditches provide conditions favorable for the growth of snails which serve as the intermediate host in the transmission of schistosomiasis. This disease threatens to become a serious detriment to public health unless adequate measures of prevention are incorporated in the government's plans for irrigation and drainage.

The population of Iraq, according to the 1947 census, is approximately 5 million; 700,000 live in Baghdad, 100,000 in Basra, and 150,000 in Mosul. An estimated 200,000 Bedouin nomads roam the desert region and the remainder live in small villages and other rural areas. The prevailing religion is Mohammedanism.

use of DDT in a residual spray operation has greatly accelerated the rate of decline.

The reduction in transmission has been impressive, but still there is danger of localized sporadic outbreaks so long as chronic carriers and capable vectors remain. The malaria control organization offers a nearly perfect setup for a rigid surveillance program in the years to come. Village visitations continue, with greater emphasis given to case finding. More effective treatment is in progress under a more rigid medical direction. With some villages becoming free of malaria, additional emphasis can be given to those which still have reported cases of the disease.

The conversion of the existing organization to one of general public health services is a logical sequence as malaria decreases in importance. The trend from specialized to general public health services is in the formative stage, with sanitarians gradually broadening their activities. Thus, the Turks, with characteristic energy and persistence, have all but conquered a disease which plagued their land long before their ancestors captured it.

Mental Defectives and Epileptics in Public Institutions

There were more than twice as many first admissions as discharges from public institutions for the mentally defective in 1954, according to the National Institute of Mental Health, Public Health Service.

New cases numbered 12,485 or 8 per 100,000 population, while 5,815 patients were discharged and 1,026 readmitted. The average daily patient load for mental defectives and epileptics combined was 138,595, with 109,931 classed as mental defectives. The range of expenditures for patient care varied considerably among the States, but the average cost per patient-year was \$1,039. Of the 157,770 patients on the institution books at the end of the year, 139,977 were listed as in residence.

The item on page 162 of the February 1956 issue incorrectly applied the figures above to public mental hospitals.

Foreign quarantine inspector at work. This service is under the direction of an American trained Iraqi physician.

ment of personnel from the Ministry of Health.

In the field of sanitation, the government, under the supervision of the Ministry of the Interior, is progressing rapidly in bringing clean water to its people. The major cities and most of the towns now have modern water treatment plants and distribution systems. However, in most of these cities and towns, personnel training and plant supervision have not yet progressed to the point where the water can be considered safe by Western standards. As a logical first step towards promoting safe water supplies for villages, the Development Board is conducting a survey of the ground waters of the country.

Less has been accomplished in developing sanitary disposal of sewage, but the government officials are acutely aware of the need and a bill has been introduced in Parliament which would

set up a commission on municipal drainage and sewerage design and construction. (The use of sanitary privies is almost unknown.)

Large numbers of villages depend for drinking purposes entirely upon irrigation water that is often highly contaminated. This water is obviously a serious health hazard.

With respect to the other aspects of public health and sanitation, the responsibility rests with the chief medical officers of the 14 liwas and the city health officers of the major cities. Such sanitation services are quite rudimentary.

Fellowship Program

As a first step in the United States assistance program, fellowships were awarded and training courses started on an empirical basis. Soon it became evident that it was not practical to plan a training program without a concept of the type of organization one was trying to build. Therefore, a proposed organization chart was designed, and soon a proposal was drafted for the training of the personnel to staff the organization. The organization chart and the training proposal were prepared by the Ministry of Health with the assistance of consultants from the United States Operations Mission, the World Health Organization, and the British Government.

The plan encompassed the training of many types of hospital personnel as well as public health and sanitation personnel. Realistic consideration to recruitment problems and possible sources of training have also been included in the plan, and detailed job descriptions have been prepared for all of the positions.

To date, 31 fellowships for health instruction in the United States have been granted as follows: public health administration (physicians), 7; hospital administration, 6; vital statistics, 3; sanitary engineering, 2; surgery, 2; pathology, 2; ophthalmology (4-month grant), 2; and 1 each in internal medicine, obstetrics, general hygiene, anatomy, ear-nose-throat, urology, and public health laboratory. Also the following 19 health fellowships have been granted for training at the American University of Beirut in Lebanon: public health nurses, 7; sanitarians, 4; laboratory technicians, 5; and hospital administrators, 3.

The government is a constitutional monarchy with an elected parliament and several ministries presided over by a prime minister. A distinctive feature of the Iraqi Government is the Ministry of Development, whose programs of economic growth are formulated by a Development Board with the Prime Minister serving as chairman. The objective of the Development Board is to use its portion of the oil revenues to develop the agricultural and industrial potential of the country in such a way as to assure a sound economy after the oil reserves are exhausted. Seventy percent of the substantial oil revenues are allotted to the Development Board to finance its economic plans. The remaining 30 percent are allotted to the Ministry of Finance for distribution to various ministries for the normal operations of the government and for social welfare, education, and health.

Health Conditions

Although it is known that health conditions in Iraq are not good, it is difficult to speak with precision because vital and morbidity statistics are very incompletely reported. The mortality rate is commonly estimated to be about 25 per 1,000 population and the infant mortality rate 250 per 1,000 live births.

Undoubtedly, the most prevalent diseases in the country are those which affect the intestinal tract: bacillary and amebic dysentery and worm infestation. Nutritional deficiencies are prevalent, but actual starvation is limited mostly to infants. Starvation of infants is prevalent and results from lack of knowledge about modern artificial feeding methods.

Although malaria is no longer endemic in Baghdad and the immediate vicinity, it is still a problem in the southern date- and rice-growing areas and in the northern mountains. Schistosomiasis is a serious problem in some localities and threatens to become more widespread unless appropriate precautions are taken in connection with the irrigation projects which are being planned by the Development Board.

Tuberculosis is moderately prevalent in Iraq, and trachoma causes much blindness, particularly in the villages. Endemic typhus fever occurs in Iraq, and epidemics of smallpox occur almost annually. Localized outbreaks of

diphtheria and meningococcus meningitis are sporadic. Hookworm infestation is prevalent in some areas. Bejel is widely distributed in some remote rural areas.

Health Facilities

Of about 900 registered physicians in Iraq, 70 are foreigners. Almost all of the Iraqi physicians are graduates of the Royal College of Medicine in Baghdad. Six years of basic medical education at the college is provided free of charge by the government. In return, the graduates are obligated for 4 years of governmental service, divided among the Royal Hospital, the military service, and general practice in rural areas.

There are fewer than 600 registered nurses. About 260 are graduates of 3-year training schools, and the remainder are graduates of 1-year training courses in small hospitals.

There are about 5,000 hospital beds in the country, or 1 per 1,000 population for the country as a whole. The major portion of the hospital beds are concentrated in the city of Baghdad. However, the capital city of each liwa has a general hospital and in some instances 1 or 2 specialized or military hospitals. Free medical care is provided in more than 90 percent of them. Nevertheless, most of the hospitals are old, poorly equipped, and understaffed. Laboratory facilities in almost all of the hospitals and dispensaries are inadequate for accurate confirmation of diagnoses.

Of the dispensaries, only a few are operated by physicians. The majority are operated by "health officials" who correspond roughly to male nurses in the United States, or by "dressers" who are men trained locally. Most of these dispensaries we would term first-aid stations. In some of the mountainous areas, mule-train dispensaries have been organized in an attempt to bring rudimentary medical care to the people.

In each of the 14 liwas (provinces), there is a central liwa hospital which, except in the Baghdad Liwa, is personally supervised by the chief medical officer who is administratively responsible to the governor of the liwa for all medical and public health activities within the liwa. The chief medical officer obtains his professional guidance, operating funds, and assign-

A home visit by an Iraqi public health nurse of the Basra project.

the entire liwa. Instruction is being given to public health nurses, health visitors, sanitarians, and health educators. Also assistance is being given in connection with public health administration and modern public health techniques to the Iraqi physicians who are associated with the program. When the field activities are well established, this project will serve as a center for formal training and for supervised field experience for personnel to staff similar projects in other parts of Iraq.

Thus far, the activities of the project have been concentrated largely upon health education and the training of personnel. Ten health visitors and 12 sanitarians have been trained, and the health visitors have been engaged in supervised field work for a year. For example, in the one month of May 1955 the public health nursing and health visitors' section gave service to 8 clinic sessions and 34 school health sessions,

made 1,457 home visits, and gave 19 group talks.

One accomplishment of this project has been the demonstration that a citizens health committee can organize and function effectively in Iraq, a country which has been relatively unaware of this civic progress. These committees are composed entirely of Iraqi citizens who elect their own officers and conduct their own meetings. One citizens committee has been working for almost a year. Its work will be the base for an aggressive health education program. Additional committees are organizing with the full support and encouragement of the provincial governor, the mayor, and the chief medical officer.

The sanitary engineer assigned to the project is studying conditions under which a proposed drainage and sewerage system for the city of Basra will be installed.

It is planned that there will be a central

An American laboratory technician teaching a class of Iraqi students.

Trainees most difficult to recruit have been those for public health administration and public health nursing. Iraqi physicians do not consider positions in public health administration financially attractive. It is also difficult to recruit for public health nursing because few graduate nurses want to take the training and few are sufficiently proficient in the English language to benefit from courses offered by the United States. Proficiency in English is essential because there are no schools of public health nursing where the instruction is given in Arabic. The teaching in the public health school at the American University of Beirut is in English.

Nurse training at the Royal Hospital, the only governmentally recognized 3-year nursing school in the country, is conducted in Arabic.

The ministry is attempting to break these bottlenecks by providing better pay for full-time public health physicians and by establishing a new nursing school. Such a school will be established with our assistance in the near future. Instruction will be given in English in the new school, and eventually instruction in nursing will be in English instead of Arabic since

there is little professional Arabic literature in the field of nursing.

All Iraqi personnel who complete courses of training either under fellowships or in the cooperative projects described below are followed up to see that they are properly placed and that their newly acquired skills are fully utilized. In addition, the physicians who have studied public health administration meet regularly as a group to discuss Iraq's public health problems and to seek solutions to the difficulties they are encountering in applying the techniques they have learned.

In all training programs it is as important to provide appropriate orientation toward democratic public health objectives for administrative leaders as it is to train professional and semiprofessional workers to do the field work. Without sympathetic and intelligent administrative leadership, the field workers cannot be fully effective however well trained they are. Therefore, a policy has been adopted of providing grants to high ranking Iraqi public health officials to enable them to visit America for carefully planned and supervised tours of American institutions and for conferences with American leaders in various fields of public health and medical care.

Basra Demonstration Project

In addition to grants and fellowships, the program provides on-the-scene training through a variety of demonstration projects.

At Basra, near the Persian Gulf, the ministry is being assisted in establishing a public health demonstration and training project. The purpose of this project is to set up, in this one liwa, a public health organization like the one envisioned in the 5-year plan.

American personnel with Iraqi counterparts fill the positions of senior health officer, sanitary engineer, sanitarian, public health nurse, and health educator. An Iraqi epidemiologist also has been provided, and the ministry has assigned three Iraqi public health nurses who were trained under our fellowship program at the American University of Beirut.

Iraqi personnel are being trained, and as they become proficient in their duties the project activities will be expanded until they take in

A home visit by an Iraqi public health nurse of the Basra project.

the entire liwa. Instruction is being given to public health nurses, health visitors, sanitarians, and health educators. Also assistance is being given in connection with public health administration and modern public health techniques to the Iraqi physicians who are associated with the program. When the field activities are well established, this project will serve as a center for formal training and for supervised field experience for personnel to staff similar projects in other parts of Iraq.

Thus far, the activities of the project have been concentrated largely upon health education and the training of personnel. Ten health visitors and 12 sanitarians have been trained, and the health visitors have been engaged in supervised field work for a year. For example, in the one month of May 1955 the public health nursing and health visitors' section gave service to 8 clinic sessions and 34 school health sessions,

made 1,457 home visits, and gave 19 group talks.

One accomplishment of this project has been the demonstration that a citizens health committee can organize and function effectively in Iraq, a country which has been relatively unaware of this civic progress. These committees are composed entirely of Iraqi citizens who elect their own officers and conduct their own meetings. One citizens committee has been working for almost a year. Its work will be the base for an aggressive health education program. Additional committees are organizing with the full support and encouragement of the provincial governor, the mayor, and the chief medical officer.

The sanitary engineer assigned to the project is studying conditions under which a proposed drainage and sewerage system for the city of Basra will be installed.

It is planned that there will be a central

health center in the city of Basra which, in addition to providing clinical health services for the people of the immediate vicinity, will provide offices for the liwa health personnel. Branch health centers will be located in the various communities of the liwa in such a way that they will be accessible to the entire population.

Environmental Sanitation Project

An American sanitary engineer has been assigned to the Ministry of Health in order to give substance to its department of sanitation.

Initially, this engineer devoted the greater portion of his time to the city of Baghdad. He supervised and trained the city's sanitarians and revised and strengthened the city's program of sanitation of public eating places. A food handlers' school was established, and instruction has been given to 850 food handlers. The engineer introduced an educational approach to restaurant inspections. In addition, he provided consultation on many aspects of the city's sanitation problems. City authorities were persuaded to operate a sanitary landfill for garbage disposal. Improved design and supervision were introduced in the construction of cesspools and septic tanks by private contractors. Practices at milk pasteurization plants were improved.

Baghdad has now acquired a well-trained Iraqi sanitary engineer who has assumed these responsibilities although our sanitary engineer continues to give guidance and technical advice. Outside of Baghdad, requests for his assistance thus far have been mostly in connection with drainage and sewage disposal problems. Plans for expansion of his activities are under consideration.

Hospital Facilities Project

The Iraqi Government intends to launch a hospital and health center construction program which will cost \$20 or \$30 million or possibly more. Since Iraq lacks the specialized personnel required to plan an efficient hospital system or to design modern hospitals, a hospital architect and a hospital administrator have been assigned to the Ministry of Health by

the United States Operations Mission. At present, they are engaged in functional studies, preliminary sketches, and cost estimates for a new Royal Medical Center (referred to locally as Medical Town) to replace the present Royal Hospital. This will include an 850-bed government hospital, a 150-bed private hospital, a central building for the Royal Medical College, and a nursing school. It is estimated that the project will cost about \$12 million.

The role of the American team is (a) to make preliminary functional studies of the proposed buildings; (b) to represent "the client" (the Ministry of Health) in negotiations of contracts with architectural firms for the production of working drawings and specifications and the supervision of construction; and (c) to represent the client in relation to the smaller projects which are designed and constructed by Iraq's Department of Public Works.

The hospital administrator assigned to the project is directly concerned with the portion of the ministry's 5-year plan that deals with the training of hospital personnel. Of special concern to him are the Iraqi personnel who have completed training in hospital administration either in the United States or at the university in Beirut. He helps with the placement of these personnel in appropriate positions and keeps in close contact with them during the period of adjustment to their new duties. It is expected that these former trainees, under the guidance of the American hospital administrator, will spearhead the improvement of hospital administration practice in Iraq.

Village Life Improvement

One program of the United States mission cuts across the various technical specialties and aims to bring about improvement in all aspects of the living standards in the villages of Iraq. Public health has an important role with respect to improvement of water supply and village sanitation, control of disease vectors, and home hygiene services.

This program is one of several types which are referred to as "impact programs." Its objective is to carry some of the simple benefits of modern technology more directly to the villagers than can usually be done through the nor-

mal operations of government agencies. Iraqi personnel are trained and then assigned to live in the villages and show the inhabitants how to improve their living conditions.

The Iraqi "rural affairs officers," who are being trained under this program, are known as multiple purpose workers. Sanitation and hygiene are important subjects in their training course, which also includes some simple methods of improving agricultural practices, homemaking, child care, and road building.

Two other projects are in operation at present. The first is the maternal and child health demonstration and training project, which has been reported in detail in *Children*, volume 2, March-April, 1955. The second project, recently instigated with American assistance, is a school for laboratory technicians.

Comments

The region which is now Iraq has been the abode of some of the world's oldest and proudest civilizations. It was the breadbasket of the Babylonian and the Moslem Empires. Its soil has provided a prosperous living for populations estimated as high as 40 million.

However, the Mongol invasions decimated the population and destroyed the elaborate irrigation system upon which the livelihood of the people depended. These invasions struck the civilization of the area with what Toynbee would call an "overwhelming challenge." The following four centuries (since 1517), under Ottoman rule, drained the people of their initiative and ambition and instilled in them a deep, abiding distrust of centralized government. In response, they devised a form of subsistence living which made it possible for them to survive under the most adverse conditions.

Since Iraq's liberation in the First World War, the country has, with British assistance,

made much progress in reviving the art of self-government (parliamentary), but much remains to be done to improve the standards of living of the common people. In recent years the new revenues derived from the exploitation of the country's oil resources give hope of a rapid acceleration in the achievement of this objective.

The United States offer of the services of experienced American personnel aims to help rehabilitate the nation's economy and assist in bringing better living conditions to the people. The Government of Iraq has welcomed this assistance and has sincerely tried to carry out its part of the cooperative agreements. That it has not been entirely successful in this is due to various factors which include: (a) its inadequate fiscal and personnel systems, which impose formidable administrative barriers; (b) the narrow base of the country's educational system, restricting opportunity, especially for girls, with the resultant scarcity of qualified candidates for training; (c) frequent and numerous cabinet changes in recent years; and (d) the great flood of the spring of 1954.

Despite these handicaps substantial progress has been made with the public health program. The public health program has been chiefly a "pump-priming" operation to encourage the granting of appropriate emphasis to preventive medicine and sanitation in the country's economic plans. The country has sufficient resources to permit it to support a completely modern medical and public health establishment. The problem has been to avoid allowing the public demand for curative medical facilities to overemphasize personal medical care at the expense of public health facilities needed.

Progress to date has been gratifying, and for the future there is justification for increased optimism as confidence in, and respect for, public health services take hold.

technical publications

The Engineer in the U. S. Public Health Service

Public Health Service Publication No. 455. 1955. 20 pages.

This illustrated brochure for the recruitment of sanitary engineers describes the wide variety of activities of the commissioned engineer officer in the Public Health Service. Qualified sanitary engineers are invited to join the Service and share in its 150-year-old tradition and progress.

Discussed are the many opportunities the Service offers in the field of environmental sanitation—water supply, waste disposal, milk and food, vector control, and the challenging new fields of air pollution and radiological health.

The various facilities including the Robert A. Taft Sanitary Engineering Center, the largest research institution in the field, are depicted. Opportunities for service overseas with the United States health missions are explained.

The booklet also delineates the role of the engineer members of the Public Health Service Commissioned Reserve in meeting emergency national health problems.

Biological Products, Revised, 1955

Public Health Service Publication No. 50. 1955. 48 pages. 20 cents.

Superseding Miscellaneous Publication No. 39, this publication lists establishments holding licenses for the preparation and sale of viruses, serums, toxins and analogous prod-

ucts, and the trivalent organic arsenic compounds.

The licenses granted establishments for the products specified do not imply an endorsement of the preparations. A licensed establishment is inspected regularly for personnel technical ability and sanitary condition of premises. In addition, manufacturing methods must be adjudged safe, and the establishment must meet requirements, specified by the Division of Biologics Standards of the National Institutes of Health, designed to insure the continued safety, purity, and potency of products.

Sources of Morbidity Data, Listing Number 3. 1955.

Public Health Service Publication No. 459. 99 pages.

The third listing of projects in the files of the Clearinghouse on Current Morbidity Statistics Projects contains descriptions of 145 projects, supplementing the 332 described in listings No. 1 and 2 (Public Health Service Publications 332 and 399).

Listing No. 3 has a section of supplementary notes on projects in listings No. 1 and 2, that represent a systematic followup on all projects in the two listings that were in progress when their descriptions were received by the clearinghouse.

In listing No. 3 there is an index by type of data collection, also an alphabetical list of principal investigators, and, for the first time, an index of organizations and institutions participating in the projects.

Because the listings of the clearinghouse are published primarily for the use of actual and potential contributors, the number of bound copies available for other distribution is limited. Tear sheets for all projects are on file, however, and these will be mailed free of charge to persons inquiring about studies of a particular type.

NIDR Current Clinical Studies and Patient Referral Procedures at the Clinical Center

Public Health Service Publication No. 456. 1955. 8 pages.

Described in this pamphlet are current clinical studies of the National Institute of Dental Research and the types of patients desired for participation in these studies.

It is intended as an aid to dentists and to others in dental schools, clinics, and health services who wish to refer patients to the institute for study and treatment at the Clinical Center in Bethesda, Md. Also explained is the procedure for referral of patients and the requirements for admission to the Clinical Center.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

Cardiovascular Disease Programs for the Community

By WILLIAM J. ZUKEL, M.D., HERMAN E. HILLEBOE, M.D., and JOSEPH T. DOYLE, M.D.

THE COMMUNITY expects leadership from the health officer in solving its major health problems; these may be infectious diseases in one area or chronic diseases in another, or both in many areas. The growing problem of cardiovascular disease, which is now responsible for more deaths in the United States than all other diseases combined, should challenge the best efforts of every health officer to seek counter measures. In New York State during 1954, for instance, cardiovascular disease was given as the cause of more than half of all deaths (see table).

Ultimate death, of course, cannot be avoided, but premature death, unnecessary suffering, and disability can often be prevented. The First National Conference on Cardiovascular Diseases (1a) in 1950 brought out the need to apply existing knowledge of cardiovascular disease control; at the same time, it was recognized that continued research is of prime importance. Much is yet to be learned about effective measures for controlling cardiovascular disease; however, the considerable experience and new

knowledge that have accumulated indicate promising tangible activities.

More than 50 diseases are known to produce myocarditis as a major or associated complicating illness (2,3). These include rheumatic fever, diphtheria, rickettsial disease, syphilis, tuberculosis, meningococemia, leptospirosis, trichiniasis, tularemia, and brucellosis. Most of these diseases have been responding well to public health measures. Rheumatic fever, too, could be removed from its place as third most common cause of heart disease by the concerted effort of private and public health physicians. Effective use of present knowledge of prevention and the early treatment of streptococcal infections could make the disease a rarity.

Atherosclerosis and hypertension remain the greatest heart problems. But even with these, there is reason for optimism that research efforts will provide at least partial measures for control in the foreseeable future.

Since the scope of the cardiovascular disease problem is so broad, every health officer can find some area for positive action. How much is accomplished may depend more on the interest and activity he can stimulate within the local medical profession and in the community than on the size of his staff or budget. Physicians will support services that benefit the patient, if these services do not infringe on physician-patient relationships. By working with the physicians, the local heart association, community leaders, and representatives of community agencies, a thoughtful appraisal can be made of community needs and a program developed to meet these needs. Although measures to meet specific needs in cardiovascular

Dr. Zukel, now chief of the Operational Research Section, Heart Disease Control Program, Division of Special Health Services, Public Health Service, was formerly assistant in medicine at the Albany Medical College, Albany, N. Y. Dr. Hilleboe is commissioner of health of New York State and professor of public health at the Albany Medical College, and Dr. Doyle is director of the Cardiovascular Health Center and associate professor of medicine at the college.

disease are in themselves important, they should relate as well to other chronic diseases in the community.

Although no two communities are identical, there are several activities applicable in most communities. Some involve action on present knowledge; others would entail studies to add to our information (see outline). A review of some of these activities follows.

Primary Prevention

Specific measures directed toward the prevention of infectious diseases, such as diphtheria, syphilis, and tuberculosis, should be applied at every opportunity. The drama of preventive measures may not match that of surgical correction of congenital anomalies, but the value of prevention is unquestionable and lasting. There are sound recommendations for the primary prevention of cardiovascular disease in the reports of the First National Conference on Cardiovascular Diseases (1*b*) and of the Chronic Illness Commission (4). Certain aspects are worthy of review here.

Congenital Heart Disease

Congenital heart disease is far from being a rare condition. Richards and associates (5) in a careful study of an unselected series of 6,053 births found 50 cases of congenital cardiovascular malformations, an incidence of 0.83 percent. Twenty-nine of the fifty cases survived 1 year, representing 0.5 percent of the total study group surviving that long. In some school surveys, congenital heart disease has been as prevalent as rheumatic heart disease (6, 7).

Of recognized public health importance is the relationship of maternal rubella infections during the first trimester of pregnancy to the development of anomalies in the fetus (8). The estimates of 100 percent risk (9) of anomalies from rubella occurring during the first 2 months of pregnancy appear to be too high, and a figure closer to 20 percent (10) is a more realistic estimate from prospective studies. Nevertheless, the gravity of the consequences has been considered by some to be justifiable reason for therapeutic abortion in women who contract rubella during the first 3 months of pregnancy (1*b*, 11).

Program Activities for Cardiovascular Disease

Prevention: primary and secondary

Community research

Education and information

Detection programs

Diagnostic services

Ancillary services: nursing, nutrition, medical social, physical therapy, vocational guidance, laboratory

Nursing homes, convalescent homes, home care

Rehabilitation

Evaluation

The American Public Health Association (12) and the Committee on Immunization and Therapeutic Procedures for Acute Infectious Diseases of the American Academy of Pediatrics (13) are in agreement on basic recommendations regarding rubella and birth anomalies. Essentially they are: Girls in good health should not be protected from exposure to rubella before puberty since permanent immunity usually follows the disease. Women in the first 4 months of pregnancy should avoid exposure to rubella if possible. Gamma globulin should be administered to women who are exposed to rubella during the first 4 months of pregnancy to provide the possible protection afforded by the induced passive immunity.

The dosage of gamma globulin presently recommended by the New York State Department of Health for intramuscular administration is from 0.2 cc. per pound of body weight to a maximum dose of 20 cc., preferably containing material from two different lots (14). This is based on the finding that the titer of rubella antibodies may vary with different lots of pooled gamma globulin (15) and that the higher dosage should be more effective in preventing rubella.

Other viral diseases during the first trimester of pregnancy have been incriminated as causing fetal anomalies, but the relationship is not yet established. Herpes simplex during the first trimester had a suggestive but perhaps coincidental relationship to the development of the tetrad of Fallot in Richards' study (5). Mumps, measles, varicella, poliomyelitis, infec-

tious mononucleosis, influenza, herpes zoster, and virus pneumonia during the first trimester of pregnancy are mentioned as reported causes of fetal anomalies in collected cases of Kaye and associates (16). Dietary deficiencies in the mother during early pregnancy suggest an association with a higher incidence of fetal anomalies, but the relationship is difficult to prove (17). Prospective studies will be needed to establish the validity of these observations.

Experimental animal studies and accumulated clinical evidence reveal that congenital anomalies in the embryo and fetus can result from extensive pelvic irradiation (18-20). Current practice usually recognizes this potential danger and elective, prolonged X-ray studies are avoided during pregnancy. Russell and Russell (19) concluded from animal studies that roentgen dosages well within the range used in diagnostic fluoroscopy might cause subtle alterations in the fetus if exposure occurred at a critical time. They recommend that irradiation of the uterus in women of child-bearing age be restricted to the 2 weeks following the last menstrual cycle to preclude the possibility of irradiation after fertilization has taken place.

Even with its limitations, our current knowledge gives encouragement that other factors might be revealed as causative agents in congenital heart disease. The epidemiological approach toward determining such possible factors is a sound one.

Rheumatic Fever

Present knowledge indicates that rheumatic fever has become a preventable disease. Several studies have shown that first attacks of rheumatic fever can be prevented when the initiating streptococcal infection is diagnosed and promptly treated with penicillin (21-23). For acute streptococcal infections, a single injection of 600,000 units of long-acting benzathine penicillin G is effective. Among 1,175 children with streptococcal infections treated with this regimen by Breese and Disney (23), no clinical rheumatic fever or acute glomerulonephritis was noted in the entire series. An attack rate of clinical rheumatic fever of perhaps 3 to 5 percent might have been expected without such treatment (24, 25). Any other dosage regimen

of penicillin is acceptable if it maintains bactericidal levels of the drug in the individual over a period of at least 8 to 10 days (26). Treatment of acute streptococcal infections with sulfadiazine has not been effective in preventing subsequent rheumatic fever (27). Sulfonamides are, however, of value as a daily prophylactic measure for known rheumatics in preventing streptococcal infections that might result in recurrence of rheumatic fever (26, 27).

A youngster who has a history of rheumatic fever may have as high as a 50 percent chance of developing a recurrence of rheumatic fever if he develops a new streptococcal infection (28). It appears that it would be advisable for persons with a history of rheumatic fever to be placed on a continuous prophylactic regimen for a period of at least 5 years from the last attack. In a report by Bland and Jones (29) on 1,000 patients with rheumatic fever and rheumatic heart disease followed for 20 years, the recurrence rate in the preprophylaxis era was approximately 1 in 5 per year during the first 5 years, 1 in 10 per year during the next 5 years, 1 in 20 during the third 5-year

From Supplement to Monthly Vital Statistics Review, April 1955, New York State Department of Health.

interval, and 1 in 70 in the last 5-year interval. Acceptable methods of prophylaxis are oral sulfadiazine, 0.5 to 1.0 gram daily, or daily oral penicillin of 200,000 to 400,000 units, or a monthly intramuscular injection of 1.2 million units of benzathine penicillin G. Specific recommendations for dosage have been formulated by the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association (26). They form a sound medical basis for a community program for the prevention of rheumatic fever.

A practical problem in such community programs has been to maintain faithful adherence to the long-term schedule of prophylaxis. The health department is uniquely able to help the physician with this problem by providing a followup service, especially through public health nurses. In some communities the health department serves as the focal point for distributing the drugs ordered by physicians (30). A roster of patients can be kept, the regularity of refill of prescriptions can be noted, and lapses from treatment more readily detected and prevented. Other communities have found that the school can serve as a focal point for carrying out the physician's prescribed regimen. This has worked successfully in Cortland County, N. Y., where such a program has operated for the past 5 years. Success in preventing rheumatic fever will depend on the faithfulness with which long-term services are maintained. Recurrences of rheumatic fever should be reduced by at least 85 percent if an adequate regimen of sulfa or penicillin prophylaxis is followed (21, 31).

Subacute Bacterial Endocarditis

A serious complication of congenital, rheumatic, or other valvular heart disease is subacute bacterial endocarditis. This disease carried a fatality rate of almost 100 percent before the use of antibiotics. Now a cure rate of approximately 75 percent is possible with proper treatment (32), but irreparable damage to the heart valves proceeds unless the invading organisms are destroyed. This disease is almost certainly preventable when prophylactic doses of antibiotics are given to persons with congenital, rheumatic, or other valvular heart disease prior to and during any operative pro-

cedure that might produce bacteremia. Common surgical procedures which may result in subacute bacterial endocarditis in persons with valvular or congenital heart disease include dental extractions; surgery about the mouth, nose, and throat; genitourinary operations; and obstetrical deliveries. Published recommendations of the Council on Rheumatic Fever and Congenital Heart Disease are good guides to follow (26). The routine application of this knowledge by physicians and dentists pays full dividends. The methods of accomplishing this can be worked out with professional groups in the community.

Coronary Artery Disease

Coronary artery or atherosclerotic heart disease cannot be prevented as yet; however, there is evidence that it is not an unalterable process (33, 34). Katz (35) has reported that early lesions of experimental atherosclerosis in the chick and in the rat can be reversed by estrogen therapy. Stare and his co-workers (36) are currently studying whether dietary alterations will reverse experimental atherosclerosis induced in Cebus monkeys.

Keys and his co-workers (37) have contributed additional knowledge that lends encouragement for the future understanding of the mechanisms of atherosclerosis. Population groups such as our own, with an average diet containing 40 percent of the calories as fats, are said to have more coronary artery disease than do population groups such as the Japanese and Bantus whose diets contain less than 20 percent of caloric intake as fat (38). Women before the menopause have appreciably less atherosclerosis (39) than do men even though they presumably have much the same diet.

As yet the data relating to diet and atherosclerosis are not conclusive enough to warrant a specific program for attempting to change diet patterns of the general public. However, for individual patients with coronary artery disease, physicians are increasingly tending to prescribe diets low in total calories and relatively low in animal fat content. The usual range of cholesterol intake in humans apparently does not affect appreciably the serum cholesterol level (40, 41). Animal fat, such as lard, produces a significant rise in human serum

cholesterol whereas corn oil substituted at the same caloric level results in a fall in serum cholesterol (42). The differing effects on serum cholesterol of animal fats and vegetable fats are being studied further (42, 43).

Physicians are finding that good nutrition services in the community are becoming as much of a need as are adequate dietary services within the hospital. Health departments can provide such services in the community through nutritionists and public health nurses trained in diet interpretation.

Hypertension

The etiology of hypertension is still unknown although many factors have been implicated in a complex interrelationship of possible causes. Some of these are the sodium ion, adrenal and pituitary hormones, neurogenic factors, and renal pressor mechanisms involving renin and other pressor factors (44, 45). Observations have been made of a frequent association of obesity and hypertension (46). While no causal relationship is claimed, it is accepted clinical practice to advise weight reduction for obese hypertensive patients (45). A favorable effect of such weight reduction on the elevated blood pressure has been demonstrated, and this is not an artifact induced by change of girth of the arm (47). Obese individuals with labile high blood pressure have a greater probability of later developing persistent hypertension than do persons who are not overweight (48).

It seems that obesity control should be part of the basic teaching of good nutrition habits early in life and profitably could begin in the elementary schools. Considerable experience has accumulated on techniques for weight reduction of obese individuals, but maintaining the achieved reduced weight level is probably the most difficult prescription to follow in all medical practice (49, 50). The physician interested in nutritional guidance for obesity control can obtain nutrition consultation services through his State and local departments of health.

Secondary Prevention

Cardiovascular diseases will likely be with us for some time to come, so we should learn

to live with them with a minimum of discomfort and disability. The continuing counsel, supervision, or treatment by a well-informed physician is the only measure known for delaying the course of the disease and preventing unnecessary complications. Both emotional and physical disability can be prevented or postponed in many ways.

Attitudes of employers, of family members, and of close associates influence the reactions of the person with heart disease toward his condition. Thus, members of the community can help reflect the increasing optimism of the medical outlook for cardiovascular disease. Fortunately, publicity and educational information regarding heart disease have, in general, avoided the fear approach; this is a sound policy to continue.

The prevention of recurrences of rheumatic fever has already been discussed. Measures for preventing the progression of congestive heart failure and for preventing sequelae of cerebral vascular disease are other community services that will aid physicians and patients alike. The common complications and disability from peripheral vascular disease also present a challenge, but present knowledge of preventive measures is limited. Rehabilitation is especially indicated for these conditions.

Congestive Heart Failure

A cursory survey of the cardiac patients in any general hospital will reveal some who are repeated visitors because of recurrent episodes of congestive heart failure. Gold (51a) found that 20 percent of congestive failure patients in a hospital had multiple admissions for the same reason. These are not as a rule the intractable patients about whom much is written but who comprise only a fraction of this group. Most of these patients have merely lapsed from an initially adequate regimen of digitalis, sodium restriction, and diuretics. Since the symptoms of congestive failure are insidious in development, the patient may be gradually accumulating edema without distress over a period of weeks before the acute episode of failure suddenly develops. This type of progression can ordinarily be prevented.

A patient who has recovered from one epi-

sode of cardiac failure can often be maintained in compensation for several years on a suitable regimen of digitalis, sodium restriction, mercurials as needed, and moderate physical activities (52). The routine is less complicated than that required for regulating a diabetic on diet and insulin. Diabetic coma is regarded as an unforgivable lapse of medical management, while acute congestive failure is shrugged off as inevitable in an "uncooperative" patient. Leiter (51b) found that one of the main reasons for poor results even in the hands of experienced physicians was incorrect diet. The physician who takes the time to educate his patient has little difficulty in maintaining the patient free of decompensation. The intricacies of the low sodium diet require that the patient learn to select foods and beverages of low sodium content and to avoid products containing sodium such as seltzer tonics and most laxatives.

Special classes (53) by dietitians, nutritionists, or public health nurses have been organized to give patients practical information regarding the low sodium diet. Patients referred to such classes by their physicians have benefited both in the exchange of information on ways to make the diet appetizing and also in the mutual feeling of support which comes from knowing that others face the same problems.

Public health nurses already are giving mercurials or diet instruction on request of physicians to a number of congestive heart failure patients who are homebound. This type of service could well be extended. Since more than half (54) of the individuals with organic heart disease may develop congestive heart failure, a program that assures optimum long-term treatment would return dividends in economic savings and in the prevention of unnecessary disability.

Cerebral Vascular Lesions

It is estimated that more than 1.8 million persons in the United States are disabled by cerebral vascular lesions (55). The majority of these are elderly individuals who have suffered a cerebral thrombosis with resulting hemiplegia. A small proportion of the disabilities are the result of cerebral embolism following rheumatic heart disease with auricular fibrillation, or of an embolus developing from a mural

thrombus after a myocardial infarction. Other uncommon disorders may also result in hemiplegia. Very few persons with intracerebral hemorrhage survive; therefore, thrombosis or embolism is usually the underlying factor in surviving hemiplegics.

Long-term anticoagulant therapy has been effective in reducing recurrences of thromboembolism in rheumatic heart disease with auricular fibrillation and a history of previous embolism (56). Studies of the use of long-term anticoagulant therapy for persons who have had cerebral thrombosis are in progress, and there is some indication that basilar artery thrombosis may be prevented by anticoagulants when administered during early stages of basilar artery insufficiency (57). Adequate laboratory facilities must be available in the community to provide reliable prothrombin determinations for physicians who wish to use the effective but potentially dangerous drugs such as dicumarol, tromexan, or similar anticoagulants.

The prevention of unnecessary disability in hemiplegics is a complex problem that requires many community health services. These patients may live for several years with alert minds trapped in dysfunctioning bodies. The speech handicaps of aphasics are particularly difficult since the patients may understand everything spoken to them but are unable to express their comprehension in words. Speech therapists are scarce in the average community. However, interested school teachers could use the instruction material (58, 59) that is available for teaching aphasics and contribute invaluable help in this aspect of the problem.

The physical therapist is the major contributor toward the physical reeducation of the hemiplegic. Destroyed function cannot be restored, but in many instances enough function remains in unaffected muscles to allow retraining for performance of basic activities. The physiatrist should be called in soon after the onset of illness to outline the physical therapy required. Rehabilitation centers that are being developed in many States will help meet the needs of hemiplegic patients; however, most communities must depend on their own resources.

The extent of disability and economic loss from peripheral vascular disease is not known, but estimates indicate it is considerable. Long-suffering patients with gangrene of the toes or indolent ulcers are commonly seen in hospital wards. Too often a series of amputations of increasingly serious magnitude follow in rapid succession. Arteriosclerotic peripheral vascular disease, varicose veins, thrombophlebitis, phlebothrombosis, thromboangiitis obliterans, Raynaud's disease, frostbite, and immersion foot are some of the more common of the peripheral vascular disease problems.

Early recognition of the disease and medical supervision are important in preventing complications in these patients. Meticulous regulation of diabetes is of great importance as is avoidance of mechanical, thermal, or chemical trauma to the extremities (60). Prevention and adequate treatment of bacterial and fungal infections, regular foot hygiene, and abstinence from smoking are other measures of general value. Instruction of diabetics in daily foot care is becoming more effective as physicians realize the importance of preventive measures. Public health nurses are also contributing further to this education through the increasing number of diabetic patients physicians are requesting them to see. The potential scope for such educational activities is seen from the fact that 20,300 public health nursing visits were made to diabetics in upstate New York during 1954 (61).

Educational materials on foot care used for diabetics should be equally useful for patients with other peripheral vascular diseases. The use of preventive measures of this type as found in standard texts (60) is a practical starting place in preventing the progression of disability from peripheral vascular disease.

Community Research

The research laboratory is traditionally expected to discover the etiology of diseases and develop appropriate therapeutic measures. However, it is well known that epidemiological studies provided knowledge for effective control of several important diseases long before the etiological factors were identified. In-

cluded are pellagra, endemic goiter, scurvy, dental caries, and retrolental fibroplasia. Epidemiological studies have demonstrated the relationship of group A beta hemolytic streptococcal infections to the subsequent development of rheumatic fever (62); the same is true of the effect of rubella on congenital heart disease during the first trimester of pregnancy. Although epidemiological studies of coronary artery disease and of hypertension are now gaining more attention, further studies are needed to determine additional factors associated with their prevention.

Elaborate research studies are out of the question for many communities, but modest field studies are feasible in most communities, especially those with a good health department. Here are some examples of problems needing further study by community groups. It has been a clinical impression that farmers, lumberjacks, and manual laborers have less coronary artery disease than do city dwellers (63). It has been suggested in studies by Morris and associates (64) that occupational groups who perform heavy physical work have lesser amounts of severe coronary disease than do sedentary groups. Other factors incriminated without adequate confirmation are diets that are high in total calories or high in total fat (34) or cholesterol foods such as milk and eggs (65), cigarette smoking (66), and the stress of modern living (67).

Carefully designed studies are needed to test and confirm these theories, and such studies will have to be done at the community level. Industries with good medical departments can contribute valuable studies which attempt to relate occupational factors to coronary artery disease and hypertension. The work of Crain and associates (68) on the incidence and prognosis of myocardial infarction among employees lends optimism to the outlook for continued employability of persons who develop coronary artery disease. The economic loss to the community resulting from heart disease is of practical importance but has not been thoroughly studied. The incidence and prognosis of heart disease in the general population in different parts of the country are still unknown for both coronary and hypertensive vascular disease.

A comprehensive study of major factors related to coronary artery disease and hypertensive vascular disease is now in progress at the Cardiovascular Health Center (69, 70) in Albany, N. Y., but less elaborate studies in the community could give valuable information on some aspects of these problems. A health officer can interest private physicians in the many facets of the heart disease problem by developing a study that will provide new knowledge on the local heart disease problem. Many resources are available to help plan and carry out local studies. These include the universities, the State departments of health, the American Heart Association, and the Public Health Service.

Education and Information

The extent of knowledge about heart disease directly influences the effectiveness of community efforts directed toward the problem. This level of knowledge includes that of practicing physicians, nurses, social workers, vocational counselors, employers, and patients and their families. Professionals, nonprofessionals, and members of the general public are concerned with some aspects of the problem, even if it is merely from personal or family experiences.

The health officer should become involved in health educational activities to the full extent of his ability and resources. Postgraduate education for physicians is a specialized form of health education and is usually best carried on through the regular channels of the medical society, medical schools, and hospitals. The health officer and local heart association, however, can often bring in special speakers or teaching aids such as films, tape recordings, or other materials that are available and continually being developed by medical schools, the American Heart Association, the Public Health Service, and other organizations. The New York State Department of Health, like several other State health departments, maintains a library of health films that are available on loan to professional and nonprofessional groups.

Information on heart disease is essential for public health nurses, nutritionists, physical therapists, medical social workers, or any other

individuals who might be brought into heart program activities. The quality of service can be only as good as the caliber of personnel and level of their knowledge concerning their possible contributions to the problem.

The judicious use of educational information for the public can be helpful when specific program activities are being developed. It would be wise to have a medical advisory committee determine the general approach to be used in acquainting the public with health information since unsuitable materials may only stimulate fear of heart disease rather than constructive attitudes or action. People do not automatically accept health programs merely from the presentation of scientific evidence. Attitudes, beliefs, values, traditions, and many other factors influence their willingness to accept or undertake actions related to their health (71, 72). The health educator who understands the problems related to heart disease can be very helpful in developing program activities in the community. Through various processes of communication, medical knowledge can be transformed into public understanding and acceptance of specific health activities, for example, prevention of rheumatic fever, early detection of heart disease, and rehabilitation.

The local health department and local branch of the American Heart Association will do the best possible job of health education if they combine their resources in personnel and mass media and conduct a joint program of health education on a continuing basis.

Change in Name of Institute

The National Microbiological Institute, one of the seven National Institutes of Health, Public Health Service, was redesignated the National Institute of Allergy and Infectious Diseases early in February 1956. Dr. Victor H. Haas is director of the institute.

The renaming of the institute reflects the importance of new research on allergies and the close relationship of such research with the study of infectious diseases. Investigations of allergy are closely allied to the science of immunology, which is also fundamental to investigation of the infectious and parasitic diseases. Recent estimates indicate that approximately 16 million persons in the United States suffer from some form of allergy and that some manifestation of allergy is experienced by at least 50 percent of all people at some time in their lives.

The institute will support long-term basic studies in these fields through grants to research scientists in universities and medical schools. A National Advisory Allergy and Infectious Diseases Council has been established to make recommendations to the Surgeon General of the Public Health Service regarding the new grant activities of the institute. The council held its first meeting March 7-8, 1956, at Bethesda, Md.

Members of the council are leaders in science, education, and public affairs. Except for two vacancies to be filled, all the members have been appointed. They are:

Drs. René J. Dubos, member of the Rockefeller Institute for Medical Research, New York; Gail M. Dack, director, Food Research Institute, University of Chicago; Edwin B. Fred, president, University of Wisconsin; Charles E. Smith, dean, School of Public Health, University of California at Berkeley; and H. O. Halvorson, head, department of bacteriology, University of Illinois.

Byron H. Larabee, president, Firestone Plantations Company, Akron, Ohio; David C. Crockett, associate director, Massachusetts General Hospital, Boston; Mrs. Rollin Brown, of Los Angeles, president, National Congress of Parents and Teachers; and John Abbink, of New York, president, American Foundation for Tropical Medicine.

Dynamic Impact of Advancing Technology on Environment and Health

By MARK D. HOLLIS

WITHIN the short period of 50 years, Western civilization has compressed more major technological changes than had occurred in all its previous 2,000 years. Since 1900 we have witnessed the birth of the automotive age, of aviation, and of mass production techniques. Developments in electronics, chemotherapy, and jet propulsion have appeared since 1930. Synthetics—apart from celluloid and bakelite, almost unknown in 1930—are now commonplace. More than a half million synthetic compounds are in production and use—in construction, in household products, in clothing, and in foods. We often speak of the 900-percent increase in industrial production since 1900 without noting that more than half of this increase has occurred since 1940. And now, to all of this, is added nuclear energy—the atomic age with its fantastic potential for good and for evil.

But by all signs, this is only the beginning. Already on the horizon are such techniques as irradiation of foods, rocket transportation, electrification of solar energy (now operating

a telephone circuit in Georgia), and a host of other potentials.

Attitudes Concerning Change

One thing is clear: In your life span there will be an avalanche of change such as we have never known.

Much of the world is unaware of what is in its grasp. I returned last month from a trip through several of the areas of the world which have been barely touched by technical advances, if at all. To me the striking characteristic in these countries was not their primitive sanitation but their inertia toward change. One senses a hopeless resignation to the open sewers and open sores, to the appalling rates of infant mortality, to decrepit old age at 40, to acceptance of drudgery, disease, and despair. We in the United States, always a Nation of restless pioneers, generation by generation, have displayed no vested interest or ingrained habits that compel us to do things in old ways, if new ways are better. Oscar Wilde said: "The longer I live the more keenly I feel that whatever was good enough for our fathers is not good enough for us."

It is this heritage that makes possible new developments so swiftly achieved that we have little time to adjust our minds to the changes and to understand their full significance. The tenor of the times is reflected in our increased living pace—at home, at work, and at play.

Mr. Hollis is Assistant Surgeon General and chief engineer of the Public Health Service. At the mid-year commencement exercises of the University of Florida, January 28, 1956, he made this address, somewhat abridged here, upon receiving the honorary doctor of science degree.

Scarcely a new product brought on the market today can expect to make the grade unless it can be advertised as doing something faster. Detergents wash clothes faster. Household equipment bakes pies, roasts meat, washes dishes, and cools houses—faster. Industrial and business machines accomplish all sorts of tasks—faster. Communication and transportation—all work and get there faster.

Yet all this timesaving has not added even a split-second to our 24-hour day. Instead, the individual is pushed at a faster and faster pace, an endless response to alarm clocks, television, and superpowered automobiles. All this leaves him little opportunity—and less time—to think, to understand himself, his fellow human beings, and the complex environment in which he lives. Yet how much we need this understanding, not only as individual men and women but also as members of families and communities, of our place among all peoples in a shrinking world. Because only through understanding can we make wise decisions as to constructive use of our unprecedented technology. And if ever we needed wise decisions this is the hour.

Science and Technology

So let us pause to recall a distinction between basic science and technology. The scientific foundations of our understanding of physical laws have been laid slowly by the world's great thinkers through many ages. Modern technology, the prompt and effective application of basic science to practical use, is a product of this era, developed largely since we were born.

Until fairly recent years there was little direct association between the basic scientist and the technologist. G. K. Chesterton, who died in 1936, wrote of this wide gap between the scientific mind and the consequences of the knowledge produced by scientific thought:

"When a man splits a grain of sand," he said, "and the universe is turned upside down in consequence, it is difficult to realize that, to the man who did it, the splitting of the grain is the great affair, and capsizing of the cosmos quite a small one."

There now exists much closer collaboration between the scientist and the technologist, and

even more significant, between both these experts and society. As a result, each scientific discovery, promptly flashed to our network of research institutions, sets off a chain reaction emitting dozens of new discoveries.

Modern industries are ready, willing, and equipped to transform the scientific report or the laboratory demonstration into new or improved products. For example, you are familiar with the rapid development of the frozen-juice concentrate industry in Florida. I never cease to be amazed at the production reports on this industry. One producer said, "We expected much, and got much more."

What Is Environmental Health?

There exists a close interplay between technology and environmental health. And this interplay becomes closer and more involved as technology moves ahead.

Some of you may ask, "What is environmental health?" This term has come into use in recent years, and no precise definition has been accepted even by the professional groups who use it most frequently. In 1948, the World Health Organization defined human health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." Paraphrasing this statement, we might say that environmental health is a state in which man's environment contributes to his physical, mental, and social well-being and is not merely the absence of environmental hazards to personal health.

We may well accept such a proposition, for man and his environment are indivisible. Ordinarily we think of man as master of his environment, molding it to meet his needs. But it is more realistic to think of the environment and man as molding and changing each other simultaneously.

Environment is a broad term and each facet has its impact on public health. For instance, many people associate alcoholism with the social environment; accidents with the psychological environment. However, let us consider environmental health as it refers to the physical environment—to air, water, food, and shelter. Of these basic essentials, air and water in particular gain importance as our changing

Dynamic Impact of Advancing Technology on Environment and Health

By MARK D. HOLLIS

WITHIN the short period of 50 years, Western civilization has compressed more major technological changes than had occurred in all its previous 2,000 years. Since 1900 we have witnessed the birth of the automotive age, of aviation, and of mass production techniques. Developments in electronics, chemotherapy, and jet propulsion have appeared since 1930. Synthetics—apart from celluloid and bakelite, almost unknown in 1930—are now commonplace. More than a half million synthetic compounds are in production and use—in construction, in household products, in clothing, and in foods. We often speak of the 900-percent increase in industrial production since 1900 without noting that more than half of this increase has occurred since 1940. And now, to all of this, is added nuclear energy—the atomic age with its fantastic potential for good and for evil.

But by all signs, this is only the beginning. Already on the horizon are such techniques as irradiation of foods, rocket transportation, electrification of solar energy (now operating

a telephone circuit in Georgia), and a host of other potentials.

Attitudes Concerning Change

One thing is clear: In your life span there will be an avalanche of change such as we have never known.

Much of the world is unaware of what is in its grasp. I returned last month from a trip through several of the areas of the world which have been barely touched by technical advances, if at all. To me the striking characteristic in these countries was not their primitive sanitation but their inertia toward change. One senses a hopeless resignation to the open sewers and open sores, to the appalling rates of infant mortality, to decrepit old age at 40, to acceptance of drudgery, disease, and despair. We in the United States, always a Nation of restless pioneers, generation by generation, have displayed no vested interest or ingrained habits that compel us to do things in old ways, if new ways are better. Oscar Wilde said: "The longer I live the more keenly I feel that whatever was good enough for our fathers is not good enough for us."

It is this heritage that makes possible new developments so swiftly achieved that we have little time to adjust our minds to the changes and to understand their full significance. The tenor of the times is reflected in our increased living pace—at home, at work, and at play.

Mr. Hollis is Assistant Surgeon General and chief engineer of the Public Health Service. At the mid-year commencement exercises of the University of Florida, January 28, 1956, he made this address, somewhat abridged here, upon receiving the honorary doctor of science degree.

In earlier years, wastes were piped to the edge of town and given only superficial treatment—often no treatment at all. Factories too were located on the edge of town with stack discharges to the atmosphere. In those days water and air resources were able to absorb community contaminants without undue harmful effects. At worst, factories produced merely local nuisances.

Changing Character of Wastes

Today, in our metropolitan and industrial complexes, the situation is vastly different. Not only is technology advancing but metropolitan population is increasing—already up 35 percent since 1940. Now a hundred million people live in metropolitan areas of the United States. And for the most part, there is no longer an edge of town. The city blends into the suburban areas, also thickly populated and industrialized; the suburbs into ex-urbia areas, where people use the same water resources and experience the same smog; and vice versa to the next city. In addition, there is the ever-increasing volume of waste. And, most troublesome of all, an increasing complexity in the character of wastes.

Modern cities, with all their diverse activities, discharge thousands of tons of contaminants to air and water every hour. In the chemical complex involving countless new compounds, the resulting actions and reactions, continually occurring in air and water, produce situations extremely difficult to measure and even more difficult to understand. The atomic age introduces an entirely new set of terms, equations, and factors. Radioactive contamination does not follow our set patterns and established formulas of dispersion, dilution, and biochemical actions. Man's ability to control this impact of waste on the physical environment will be a significant factor in future metropolitan growth and development.

By all of this I do not mean to imply that we can quantitate the effects on personal health of contaminants in our physical environment. There is much we have to learn on this score. However, in many areas, these contaminants are causing physical discomfort, economic blight, and agricultural damage. But remem-

ber we are talking about accelerating technology. When we project present trends over the next two decades, the concentrations of contaminants in air and water do have a sobering implication—not only with respect to personal health but even more so to mental and social well-being. We must develop the understanding and remedial practices now to minimize these future difficulties.

What we need most is a better understanding of behavior and effects of contaminants in air and water. To produce this knowledge will require a much broader research effort. Universities and other research institutions should assume leadership in this effort.

On the industrial side, industry officials have an understandable reluctance to accept blame for all the atmospheric and water pollution. Actually, the responsibility is about evenly divided between industrial operations, per se, and public use of the fruits of industrial technology. Air is contaminated by the family car, home fuels, rubbish burning, and the like. Water is contaminated by home laundries, dishwashers, garbage grinders, and so on. From my experience, I am convinced that responsible industry is willing to use its research facilities to adjust its processes in line with a sound control plan. A prerequisite, however, is to know specifically what contaminants from industrial processes are hazardous and at what concentrations. And in our changing situation this is quite a task.

It is obvious that technology has created many problems in environmental health. It has, on the other hand, contributed much to the improvement in our well-being and comfort. It has given us the highest average standard of living the world has ever known.

It has been of direct assistance in providing the United States with remarkably safe public water supplies, by far the best in the world. It has improved food processing and packaging, housing, insect control, and a host of other environmental health measures.

Indirectly, the potential of cheap power from nuclear sources will place in the hands of the engineer a much wider range of possibilities. Reclamation of sea water, talked about for ages, is moving toward practical reality with such developments as the permionic membrane.

technology shapes our Nation more and more into a complex of metropolitan centers.

Water Resources

Concentrations of people in a technological environment are bound to create all sorts of wastes which pollute and deteriorate the air and water resources. In nature, both air and water have an unusual capacity for absorbing and purifying man-made pollution—up to a point. So long as human activity does not overtax nature, air and water resources remain essentially clean and safe. In our accelerating technology, we do overtax these resources. Corrective practices to preserve a balance acceptable to all interests are not always easy.

Across the Nation, our water resource is becoming a problem of top priority. Available supplies are being increasingly taxed. In many areas, shortages already threaten to halt further expansion. The water problem is one of increasing demands, seasonal shortages, floods, and pollution.

The average urban dweller uses 150 gallons of water per day. Thirty years ago, one person used only 20 gallons per day. There were then few if any laundromats, dishwashers, and air conditioners. The water that goes into production of things you eat and wear and use raises the national per capita requirement to 1,500 gallons per day. By 1975, these water demands will double—expressed on an annual basis, a million gallons per capita for a population of about 200 million.

Industries that need large amounts of water, and that is most of them, will go where it is. And by and large the population will go where industry goes. It is just as simple as that and at the same time just as complicated from the standpoint of future economic, social, and environmental adjustments.

Water Conservation

The mere availability of water represents only half the picture. As water use increases, pollution increases. What we face, therefore, is a vicious cycle—more water needed, to support more activity, to produce more wastes, to pollute more water. The answer involves a

variety of water conservation measures. Of these, pollution abatement is essential to permit re-use of the water as streams flow from city to city. And remember that 80 million people depend on surface streams for their drinking water.

When I was a boy, three expressions often used were: "cheap as dirt"; "free as water"; and "easy as breathing." The zooming prices of real estate knocked out the first. Water shortage is taking care of the second. And now even the third may have to be qualified. In some areas, the air is not so easy to breathe.

Air Pollution

Twenty years ago, community air pollution was quite localized and was primarily a problem of smoke abatement. Then in 1948, 5 smoggy days at Donora, Pa., made thousands ill and caused at least 20 deaths. In London, England, in 1952, 7 days of smog implicated air pollution in 4,000 deaths. These episodes should not be dismissed entirely as freak situations.

Less dramatic smog episodes build up from time to time in most of our metropolitan areas. The reality is that the community air supply, like water supply, has limitations. Florida has her water problems, but California leads in the smog problem department. Los Angeles is the best example of a city in our changing technology that is overtaxing its air supply.

In highly developed areas we simply cannot go on forever spewing more and more complex contaminants into the atmosphere without inevitable consequences to public health and community well-being.

We must expect some deterioration of community air resources in this age of ours. The job, as with water, is to limit depreciation in keeping with the entire development of the area.

You may ask, "Why this sudden concern about community wastes reaching air and water?" A popular belief is that it should be simple and easy to purify such wastes before discharge. On the contrary, proper control is both complex and expensive. Water pollution abatement alone will cost a billion dollars a year of somebody's money.

What Is Happening to Sponsored Training for Nurses?

By DONNA PEARCE, B.S., R.N.

IT IS ESSENTIAL that the professional competency of health workers keep pace with the expanding scope and increasing complexity of modern public health if a high quality of public health practice is to be maintained. Recognizing this principle, the authors of the Social Security Act of 1935 included among its purposes provision for the training of public health personnel. In the early years of the program authorized by this act, designated amounts of money were allotted to States for the specific purpose of developing qualified professional and technical personnel. Later, the State health departments allocated to training whatever amounts from Federal funds they deemed appropriate. In addition, limited funds from State and local appropriations have been used for training purposes. Such training, financially supported in whole or in part from Federal, State, and local health funds, has come to be known as sponsored training.

Nurses, representing the largest single group of professional workers in health departments, have figured prominently as recipients of sponsored training. Of the 6,674 trainees who were sponsored for academic study in public health

during the years 1936 through 1944, 4,032 (60 percent) were nurses (1).

Federal grants-in-aid for health work reached their peak in fiscal year 1951. For grant-in-aid funds administered by the Public Health Service, the peak year was fiscal 1950; after that year, there was a rapid decline each year through fiscal 1954 (2). With this decline in Federal grants, there has been a growing professional concern as to the status of the sponsored training program. Because of this concern, an attempt has been made to find out what is happening to sponsored training for nurses.

For this study, data for an 8-year period, fiscal years 1947 through 1954, were analyzed. Data on the number of nurses who had received sponsored training during each fiscal year 1947 through 1952 had previously been obtained by the Division of State Grants, Public Health Service. For fiscal years 1953 and 1954, comparable data were obtained by the Public Health Service regional consultants through visits and correspondence with State health departments. (In this report, the term "State" includes the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands.)

The data cover all full-time accredited training for periods varying in length from "less than 6 weeks" to 12 months. Accredited training refers to study for which academic credit is granted by a school of public health or by a university or college offering a public health

Miss Pearce is assistant chief of Public Health Nursing Services, Division of General Health Services, Public Health Service. She has been with the Public Health Service since 1936.

Weather modification, although still in the exploratory stage, has intriguing possibilities. Automation, too, will find increasing application in the environmental health field.

Now to shift gears for a moment. The engineering and technical aspects of pollution control likely will be less difficult in the long run than the related political, economic, and legal considerations. Pollution of air and water more and more influences the patterns of metropolitan growth and land use. The degree of regulatory control, how it is applied, and especially where it is centered, raises important and fundamental questions.

Effects of pollution are seldom limited to one political jurisdiction. Always difficult is the question of financing necessary remedial measures. Even more difficult is the process of ob-

taining agreement among various interests for the best use of environmental resources. There is real need for public awareness and for public understanding. The situation cannot be corrected by merely opening a window or turning a valve.

If the pollution problems of the future are to be met and managed, coordinated city and regional planning must be the basis. This must integrate the social, political, legal, and economic factors with the technical ones. Each State needs to appraise its problems realistically and to develop a framework which will foster a partnership participation by other public and private interests. This will require a degree of effort much better organized and much better understood by the public than are our present practices.

Research in Hospital Facilities Field

Grants for research projects to develop new knowledge about hospitals, health services, and health facilities were awarded in February 1956 by the Public Health Service to Yale University, Sinai Hospital, Baltimore, St. Mary's Hospital, Evansville, Ind., Health Insurance Plan of Greater New York, and the American Hospital Association. The grants were awarded, upon recommendation of the Federal Hospital Council, from the recent appropriations under the Hospital Survey and Construction Act for research in the hospital facilities. Eleven grants were also awarded in December 1955.

Yale University will study factors which can be used to achieve maximum functional efficiency in hospital architectural design.

The Sinai Hospital project will demonstrate the extent to which the shortage of professional nurses can be alleviated by employing and training floor managers and general aides for nonprofessional hospital duties.

St. Mary's Hospital will evaluate its new plan to provide more individual care for patients and will demonstrate the reorganization and education necessary to success of the plan.

HIP will analyze available statistical information to determine the influence of a comprehensive medical care insurance program on hospital admissions, patients' length of stay, quality of service given, and hospital costs.

The American Hospital Association study will be a basic analysis of accomplishments over the past decade in planning and building hospitals and health facilities, including the effect of the Hill-Burton program, for the purpose of establishing new scientific guides to planning for future hospitals, nursing homes, rehabilitation centers, and diagnostic and treatment centers.

In interpreting the figures for number of nurses trained, however, variations in the proportion of long-term training periods to short-term periods must be considered. For example, of the 1,082 trainees in Massachusetts, only 16 received training for 7 to 12 months, whereas, of New York's 984 trainees, 426 received training for this length of time. California and North Carolina afford another example. Both of these States fell into the 100-399 category, but California reported that 104 of its 285 trainees received 7 to 12 months' training, whereas North Carolina had only 55 of a total of 296 trainees in this group.

Further analysis of the data for fiscal years 1953 and 1954 shows that 35 States sponsored training for periods of 7 to 12 months in 1953, whereas only 23 sponsored that type of training in 1954. One hundred fifty-eight nurses received training for 7 to 12 months in 1953, and 124, in 1954.

The Problem

The data presented show that since 1949 there has been a steady decrease in sponsored training for nurses in the United States as a whole, though not necessarily in every State. This decrease is a matter of real concern in view of the need for a continuation and expansion of training. According to the Public Health Service's 1955 census of public health nurses, only 42.2 percent of the nurses employed in State and local official health agencies on Jan-

Table 2. Number of States and number and percentage of nurses trained according to the range in number of nurses who received sponsored training, fiscal years 1947-54

		Number	Percent
Total-----	53	6, 194	100. 0
400 or more-----	12	2, 030	32. 8
100-399-----	12	2, 557	41. 3
50-99-----	12	938	15. 1
Less than 50-----	27	669	10. 8

¹ Numbers of nurses trained by these States were 984 and 1,082.

Table 3. Number and percentage of nurses in State and local official health agencies who have had approved public health nursing education, 5-year intervals, 1940-55

Year	Number nurses employed	Nurses with 1 year or more of public health nursing education		Rate of increase in percentage
		Number	Percent	
1940-----	9, 347	2, 151	23. 0	-----
1945-----	11, 414	3, 395	29. 7	29. 1
1950-----	13, 594	5, 064	37. 2	25. 2
1955-----	14, 152	5, 969	42. 2	13. 4

uary 1 had had 1 year or more of public health nursing education.

Although there has been a decrease in Federal funds for training, these funds are not the only means of providing adequate training for public health nurses. The number of collegiate schools offering educational programs for the preparation of nurses for beginning positions in public health increased from 3 in 1947 to 33 in 1956 (4, 5). A few States are exploring the use of extension courses from universities with approved public health nursing programs as a means of improving the training level of currently employed nurses. Also, two States have obtained funds from their legislatures for the training of a limited number of public health nursing personnel, and still others plan to request such funds. In the 24 States in which universities with approved programs of study in public health nursing are located, nurses may be able to pursue their studies on a part-time basis. Greater efforts along these lines, particularly the use of extension courses, should help to offset the lag in sponsored training. However, still other methods of preparing nurses for public health work may have to be worked out.

The effect of the decline in sponsored training on the qualifications of nurses employed for public health work is not readily apparent, but a few facts that may be indicative can be cited. The percentage of nurses in State and local public health agencies who have had 1 year or more of public health nursing education was greater on January 1, 1955, (42.2 percent) than it was 2 years earlier (40.5 percent). However,

Table 1. Number and percentage of nurses trained, by length of training period, and number of States participating in sponsored training for nurses, fiscal years 1947-54

nursing program of study approved by the National League for Nursing.

The Trends

A total of 6,194 nurses received training during the 8-year period, as shown in table 1. This figure, however, does not necessarily represent the number of individual nurses, since some nurses may have received more than one period of training. For example, California has reported that 29 nurses received stipends for more than one type of accredited training during a 16-year period (3).

The peak year for sponsored training, in terms of both the number of nurses trained

Number of nurses who received sponsored public health training, by length of training period, 1947-54

and the number of States that sponsored training, was 1949 (see table 1 and chart). Each year since that date, there has been a steady decline in the number of nurses receiving training. From the year 1951 to the year 1954, there was a marked decrease.

The largest percentage (53.3) of the nurses received training for 6 weeks to 6 months. However, the percentage of those sponsored for 7 months to 12 months increased in both the years 1953 and 1954.

Of the 53 States, only 4 failed to sponsor training in 1949. In 1954, this number had grown to 12.

Table 2 shows that there was a widely varying range among the States in the number of nurses trained. Two States trained 32.8 percent of all the nurses, whereas 27 States trained only 10.8 percent. A review of the figures for individual States confirms the expectation that, in general, those with large metropolitan areas employing large numbers of nurses were the ones which trained the greater number of nurses. Massachusetts, with 1,082 trainees, and New York, with 984, were the two States that trained 400 or more nurses. All of the 18 States with a population of less than 1 million are included in the group that trained less than 50 nurses. And of the other 9 States in the less-than-50 group, 6 had populations of 1 to 3 million and 3 had between 3 and 4 million.

Association of Vitamin B₆ Deficiency With Convulsions in Infants

By E. M. NELSON, Ph.D.

ONE WAY in which the Food and Drug Administration protects the consuming public is by monitoring the recovery from trade channels of any product, food, drug, or device that is found unsafe for use.

In 1953 such a program related to the occurrence of a series of cases of convulsions in infants that had been maintained on an infant food called SMA Liquid Formula (for convenience termed SMA liquid). The Food and Drug Administration's part in correlating the observations on these cases and in concluding that the condition was the result of a deficiency of vitamin B₆, although discussed at a conference on vitamin B₆ in human nutrition (1) and referred to by May (2), is not reflected in several other published reports of these cases (3-7).

Through its inspectors, the Food and Drug Administration assembled hospital records of a large number of affected infants. After careful study of these records by its medical and scientific staff and consideration of information gained from the manufacturer of the SMA liquid, particularly with respect to changes in composition of the product, it was possible to recognize interrelationships not apparent to the pediatricians who attended the individual cases.

Although at the time a confidential state-

ment containing this information was submitted to the National Institutes of Health, the Food and Nutrition Board, and the Council on Foods and Nutrition of the American Medical Association, it may be well to set forth, for a wider audience, the sequence of events that led to a recognition of the relation of vitamin B₆ to the infant convulsions. It is hoped that this will encourage prompt reporting of any unexplained disease condition that may be related to ingestion of a food or use of a drug, thereby enabling the Food and Drug Administration to take remedial steps at the earliest possible stage to safeguard the public.

Early in December 1952, the Food and Drug Administration received a letter from an Arkansas resident, a trained nurse, whose 3-month-old infant had developed convulsive seizures. She gave a complete and informative case history of her child, who had been fed SMA liquid from birth. The attending pediatrician apparently suspected the condition was associated with SMA liquid because he immediately changed the formula to evaporated milk and Karo syrup. Complete recovery from the convulsions resulted from this change. The mother then learned of eight similar cases in her community, all associated with the use of SMA liquid. All of the infants recovered from convulsions following a change of formula.

A short time later the director of the Arkansas Division of Food and Drug Control discussed the problem with our St. Louis district office, asking if we had received consumer com-

Dr. Nelson is chief of the Division of Nutrition of the Food and Drug Administration, Department of Health, Education, and Welfare.

a comparison of the figures for 5-year intervals since 1940, in table 3, shows a definite deceleration in the rate of increase in the percentage of nurses with 1 year or more of public health nursing education.

Summary and Conclusions

Data for an 8-year period, fiscal years 1947 through 1954, show a steady decrease in the number of nurses receiving sponsored full-time accredited training since 1949. The decrease is more marked for the years 1951 through 1954 than for 1949 and 1950. Although the numbers of nurses trained were smaller in 1953 and 1954 than in previous years, the percentage of long-term (7 to 12 months) training periods increased in both years.

The number of States not sponsoring any training for nurses has increased since 1949. In 1949, 4 States did not sponsor training, and in 1954, 12 did not.

As might be expected, there was a wide variation among the States in the number of nurses trained. Twenty-seven States each sponsored less than 50 trainees. Two States each sponsored 900 or more.

The States are making some effort to make up the loss of Federal funds through State appropriations and through use of extension

courses from universities. The increase in the number of collegiate basic nursing schools approved for the preparation of nurses for beginning positions in public health nursing is another encouraging sign.

However, the decided slowing up in the rate of increase in the percentage of qualified nurses employed by State and local official agencies indicates that greater efforts will have to be made to offset the lag in sponsored training. In addition, ways must be found to extend and intensify training efforts at a rate consistent with the need to overcome present deficiencies and to meet future demands.

OVR Appoints Advisers on Training Policy

The Office of Vocational Rehabilitation has appointed an Advisory Committee on Training Policy to help solve the nationwide shortage of persons trained to work with the handicapped.

The training program was established by Public Law 565, 83d Congress, in 1954 to increase the available supply of professional personnel whose skills are required in the vocational rehabilitation of disabled persons.

In the initial phases of the program, Federal grants have gone to educational institutions to help meet part of the cost of establishing or expanding curriculums in the shortage fields. Grants also have been made to individuals in such areas as social work, occupational therapy, psychology, nursing, rehabilitation center direction, rehabilitation counseling, medicine, and work with the visually and aurally handicapped.

or requirements of the infants for this vitamin? And second, why should the deficiency occur with SMA liquid and not with SMA powder which had the same composition?

The Solution

The replacement of coconut oil by palm oil in the SMA products was based on the demonstration that this change resulted in stools that, in many respects, more nearly simulated the stools of breastfed infants. A substantial change was also observed in the intestinal flora, with a marked increase in numbers of *Lactobacillus bifidus*. Obviously, either the population of organisms requiring B₆ may be increased or the population of organisms that produce vitamin B₆ reduced as a result of this change in the fatty constituents of the product. Three studies reported in 1938 show an important relationship between vitamin B₆ requirement and the fat in the diet with particular reference to the nature of the unsaturated fatty acids present (9). Witten and Holman (10) have presented evidence that in the rat there is a need for pyridoxine for the synthesis of the more highly unsaturated fatty acids.

Experiments in our laboratory had indicated that although pyridoxine hydrochloride is stable when autoclaved at 15 pounds pressure at a pH of 7, the vitamin B₆ in natural products is reduced substantially by such heat treatment. Pyridoxal and pyridoxamine, forms of vitamin B₆ that occur in food, are types of compounds known to react, upon heating, with amino acids and sugars to form a complex which the animal cannot fully use (11, 12). SMA liquid is subjected to a process of heat sterilization, but SMA powder is not. Therefore, the liquid product may be expected to be lower in vitamin B₆ content than the powder.

In examining SMA liquid for vitamin B₆ content, we were unable to obtain satisfactory results because the chemical method in use for the examination of pharmaceutical products was not applicable to milk products. Attempts to produce convulsions or other evidence of vitamin B₆ deficiency in rats were unsuccessful since the low protein and high lactose content of the product are not adapted to the nutritional requirements of the rat.

More recent analytical evidence has clearly demonstrated that SMA liquid contained a lower level of vitamin B₆ than similar liquid infant formulas, and less than the amount found in the SMA powder. This confirmed our suspicion based upon knowledge of the composition and effect of processing.

A careful resurvey of the case records of the infants affected showed that in the few instances vitamin supplements had been used none of them contained vitamin B₆.

The general causes of convulsions in infants and the plausibility of the explanation offered in this instance were discussed with Dr. Irvin Kerlan and Dr. Leo Parmer of the FDA Division of Medicine. This discussion led to the referral of some of the case histories to Dr. L. Emmet Holt since he and his associates (13) had reported studies of vitamin B₆ deficiency in infants. After reviewing these cases, Dr. Holt expressed the view that the symptoms described resembled those he had observed. The Division of Medicine then urged pediatricians to test clinically the effect of pyridoxine hydrochloride in infants showing SMA convulsions without changing the feeding formula.

Early in May investigations of hospital records revealed the occurrence of more than 50 cases of SMA convulsions in the vicinity of Lancaster, Pa. Additional occurrences were reported at Walter Reed Hospital in Washington, D. C., brought in from widely separated Army installations. Also, called to our attention were reports of three new cases in areas where it was thought the offending product had been replaced by a new formula. A more effective and complete recall of codes under suspicion began on May 15. Two weeks later a nationwide check by the Food and Drug Administration to determine the thoroughness of this recall indicated that it was reasonably complete, although there were instances in which confusion arose in identifying the codes and in which there was some uncertainty about the amounts in the hands of individual purchasers. More than a million cans of the suspect product were removed from the market.

On May 29 the Food and Drug Administration was advised by telephone that Dr. Charles D. May of the University of Iowa had treated an infant showing SMA convulsions by intra-

plaints about SMA liquid. The manufacturing firm, we learned, was aware that the product was associated with infant convulsions. Of the 12 cases reported to the firm the majority had occurred in Arkansas and northern Texas, and the firm attributed the condition to a change in mineral content of water used to dilute the product for feeding. There had been a severe drought in the Arkansas-Texas area, and the attention of the firm was focused on a possible mineral imbalance that might cause the tetany-like syndrome.

Accumulative Evidence

In investigations during January and February of 1953, the Food and Drug Administration developed the following facts:

1. More than 50 cases of so-called SMA convulsions had occurred.

2. At this stage the majority of cases had been found in the Arkansas-Texas area.

3. Invariably the sick infants had been fed SMA liquid with no vitamin supplements. Similar symptoms and physical signs were noted in the affected infants. These included hyperirritability (particularly sensitivity to noise), diarrhea, and vomiting (frequently projectile), followed by convulsive seizures lasting from one-half to 5 minutes, and recurring from once or twice daily to as many as 11 times daily. Rectal temperatures ranged from 99° to 101° F.

4. The convulsions appeared in infants ranging in age from a few weeks to nearly 1 year.

5. The formula for SMA, both powder and liquid, had been changed some time prior to January 1952 by replacing the coconut oil in the fat by palm oil.

6. All cases of convulsions were traced to the new SMA liquid formula by codes containing the letters "H" or "I".

7. In every case reported there was relief from the convulsions when the food formula was changed.

8. No cases of convulsions were reported from the use of powdered SMA, which had the same basic composition as the liquid.

9. Sedatives relieved the convulsions some, but no other medication was effective.

10. There was no clue as to the causative agent

from chemical examinations of blood and urine or from clinical tests or clinical trials.

11. Samples of the product were found to be sterile.

12. Chemical examination of the product revealed nothing unusual.

13. Many of the infants whose case records came to our attention had been under the care of pediatricians, and thorough studies had not established the etiology of the convulsions.

14. Records of such cases were not found in those larger cities where hospitals were surveyed by food and drug inspectors.

Late in March 1953, in the Food and Drug Administration, the files on this subject were referred to the Division of Nutrition for study. It was noted that the irritability and convulsive seizures described in the case records resembled the symptoms in rats from mothers on a vitamin B₆ deficient diet that had been observed in the division's laboratories (8). The rapidity of the infants' response to a change in the formula was also characteristic of the animals' recovery from symptoms of deficiency with a change to an adequate diet. Such a prompt response is not usually observed in the treatment of a toxic condition.

The composition of SMA liquid was also a basis for suspecting nutritional deficiency. The product was made from skimmed milk to which fats, lactose, vitamins A, D, C, B₁, B₂, and niacin, and potassium carbonate and ferrous sulfate were added. The reduced proportion of milk solids was supposed to provide a level of protein simulating that of mother's milk, although with such modification the amounts of water-soluble nutrients of milk, including vitamin B₆, were similarly reduced.

Dr. O. L. Kline of the Division of Nutrition was the first to associate the symptoms observed with vitamin B₆ deficiency and to offer an explanation that was in harmony with all of the facts developed. That was in March 1953, more than 6 months after the first cases occurred and after 50 or 60 cases had been treated by physicians in many areas of the country. But if vitamin B₆ deficiency was the true cause of convulsions in the infants, two questions had to be answered: First, in what manner could the substitution of palm oil for coconut oil influence the vitamin B₆ content of the product

PHS films

Embryonated Egg Techniques for Virus Studies

35 mm. Filmstrip, black and white, sound, 11 minutes, 59 frames, 1955.

Audience: Trainees in virology techniques, virus laboratory directors, and technicians.

Available: Loan—Public Health Service Communicable Disease Center, 50 7th St. NE., Atlanta 23, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Serving as an introduction to embryonated egg methods for isolating viruses in virus laboratories, public

A Plant Health Program

35 mm. Filmstrip, sound, black and white. 14 minutes, 54 frames. 1955.

Audience: Health department personnel, physicians, nurses, management, and labor.

Available: Loan—State health departments; Public Health Service regional offices; and Occupational Health Program, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington 25, D. C. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Interest in employee health programs is greater than ever before, and such programs are being developed in increasing numbers.

Management, labor, and the health professions are all affected, directly or indirectly, by this development. Financed by management, employee health services are provided at, or through, the place of work. More and more, they are being recognized as an indispensable means of keeping the worker healthy and on the job.

This filmstrip tells the story behind employee health services. By taking the viewer to a printing plant in Louisville, Ky., to watch an employee health program in operation, it helps to answer such questions as: Why are employee health programs being established? What services do they provide? What do they accomplish?

Emergency immunization carried out as a flood relief measure.

piets work carried out by the Communicable Disease Center and other disaster relief agencies during flood conditions.

It documents the efforts of local, State, and Federal health agencies

muscular administration of pyridoxine hydrochloride, while maintaining the infant on the SMA liquid. The infant recovered completely from convulsions. This report was confirmed by letter from Dr. May a few days later. Confirming reports from other investigators followed within a short time. With confirmation of the relationship of SMA convulsions and vitamin B₆ intake in infants, the manufacturer added pyridoxine hydrochloride to the product. It appears that several weeks were required for complete replacement of old stocks, since we learned of a few cases of the illness as late as September 1953, even after the palm oil was eliminated and the old formula reestablished (14). In the succeeding 2 years no additional occurrences of convulsions were reported.

It is significant that the majority of cases of infant convulsions occurred in rural areas rather than in the larger cities where the large proportion of infants are under the care of pediatricians. The prevailing practice by many pediatricians of supplementing liquid formulas with solid foods and vitamin preparations at an early age may not be followed in some rural areas. It is significant, also, that more than a hundred cases of vitamin B₆ deficiency occurred in this country before the condition was recognized as a deficiency disease.

With constant improvement in food processing, acceptable methods are needed for determining the nutritional adequacy of infant foods. For products in which the lactose is increased to simulate mother's milk, the classical biological test with the rat is impracticable because of intolerance to lactose.

The Food and Drug Administration is in a particularly favorable position to assist public health officials and the medical profession in bringing under control disease outbreaks or unusual reactions that are related in any way to the use of foods or drugs. With its investigational authority and its experienced investigational staff, facts may be collected without delay for review by the medical and scientific staff. It would be helpful if there were prompt reporting to the Food and Drug Administration of occurrences of unexplained disease con-

ditions or unusual reactions, particularly where association with the use of a particular food or drug is suspected. In such reports it is very helpful to have the complete case history and the codes or batch marks of the suspected product.

Beneath the kitchen sink may be a handy place for storage, but it's also within reach of busy little hands. "Protect Your Family Against Poisoning" reminds us to keep all drugs, poisons, and other household chemicals out of reach of children and away from foods . . . to safeguard brightly colored capsules and tablets that look like candy . . . to warn youngsters not to eat or drink any drugs and chemicals they find.

Turn to next page for text of leaflet.

Protect Your Family Against Poisoning

By IRVIN KERLAN, M.D.

MORBIDITY and mortality statistics reveal a high frequency of poisoning from accidental ingestion and other types of misuse of drugs and household chemicals by young children. Parents need to know more about how to protect their families from such accidents.

The prevention of accidental poisoning in the home has been an active undertaking of the American Academy of Pediatrics Committee on Accident Prevention, the American Medical Association Committee on Toxicology, and the American Public Health Association Subcommittee on Chemical Poisons.

Government representatives of the Public Health Service, the Food and Drug Administration, and the Agricultural Research Service of the United States Department of Agriculture are members of the committees. The National Safety Council, the American Red Cross, pharmaceutical organizations, drug manufacturers, medical societies, health departments, insurance companies, and others concerned with the safe distribution of drugs are also engaged in averting misuse of drugs and household

chemicals through label warnings, directions, special packaging, and educational programs.

Although gains are to be expected through special educational efforts and informative labeling of drugs and economic and caustic poisons, further progress can be made through a leaflet which may be prominently placed in the bathroom or kitchen where it will serve to remind the family how to safeguard the daily handling and storing of the many potentially harmful substances so prevalent in the home.

This thought led to the publication of "Protect Your Family Against Poisoning" as a pilot project of the Food and Drug Administration to encourage use of the pamphlet by health groups, food and drug manufacturers and distributors, leaders in safety education, and publishers, in reaching persons in the home. The Administration will gladly grant permission for reprinting the circular.

Almost all 10,000 copies of the circular printed in November 1955 have been distributed. The leaflet has received many commendations for its practical usefulness. So far, it has been reproduced or cited in a number of health journals and pharmaceutical publications. It has been presented on radio and television shows and mentioned in speeches by government officials. The National Safety Council has reprinted the pamphlet and so have State, county, and city health departments.

Through the reprinting by one pharmaceutical wholesaler in its safety booklet, 1,250,000 copies will become available. An estimated half million copies have already been printed by *FDC Reports* and *FDC Drug Letter* for distribution by retail druggists to their customers.

Dr. Kerlan, the author of "Protect Your Family Against Poisoning," is associate medical director, Food and Drug Administration, Department of Health, Education, and Welfare. The photographs on the opposite page are provided through the courtesy of Dr. Charles M. Cameron, Jr., associate professor of public health administration, University of North Carolina School of Public Health. The pictures are of his own children.

Local health departments in California are increasing their services and activities to meet the needs of the chronically ill in their communities.

California's Chronic Disease Activities

By LESTER BRESLOW, M.D., M.P.H., NANCY OTT, M.P.H., and VIVIAN CHIN, B.S.

IN 1950, the California Conference of Local Health Officers adopted in principle a guide, Chronic Disease Control Program in Local Health Departments. This guide defined some chronic disease control activities which local health departments might incorporate into their regular programs. Suggested activities in control of cancer, heart disease, diabetes, obesity, crippling conditions, and chronic alcoholism were listed. For each of these categories, items were suggested which "can be incorporated into most current programs," and which "could be added to many current programs."

By 1953, interest in this new area of public health endeavor had developed to the point that the conference requested the California State Department of Public Health to survey current local health department activities in the field. The bureau of chronic diseases undertook this task during the first 6 months of 1954, in cooperation with the department's consultants in the several public health specialties—health education, laboratories, nutrition, public health nursing, records and statistics, and social serv-

ice—which most closely pertain to chronic disease control. Advice and assistance were also obtained from a committee of the conference of local health officers, and from the division of local health services in the State health department.

A form was designed to obtain information on (a) general activities (special studies and projects in the chronic disease field, liaison with voluntary health agencies, participation in development of community services for chronic illness); (b) case-finding services for chronic disease; and (c) activities in the six special public health fields mentioned above. These three categories included 45 separate items.

The information was obtained in two ways. In some instances, individual consultants of the State health department gathered data from the local health departments in the course of their regular visits. In about half the departments, the data were obtained in a group conference, in which the consultants met with the local health officer and his staff, at the request of the health officer. In each case, a physician from the State health department recorded the information in the first two categories—general activities and case-finding services. A departmentwide meeting of the local health department was devoted to this survey in several counties.

The survey covered 49 of California's 52 full-time health departments. For local reasons, such as temporary absence of the health officer, the information was not obtained for three departments. A summary of the data

Dr. Breslow is chief, Miss Ott is health education consultant, and Miss Chin is assistant public health analyst, bureau of chronic diseases, California State Department of Public Health, Berkeley, Calif. Dr. Breslow is also chairman, Subcommittee on Chronic Disease and Rehabilitation, Committee on Administrative Practice, American Public Health Association.

Text of Pamphlet on Poisoning

Keep this where you will see it often.

- In the event of an accident, immediately call a physician or the nearest hospital.

- Keep all drugs, poisons, and other household chemicals out of the reach of children and away from food.

- Lock up all dangerous substances.

- Do not store poisonous or inflammable substances (kerosene, gasoline, rat poisons, and so on) in food or beverage containers.

- Read all labels and carefully follow "caution" statements. Even if a chemical is not labeled "poison," incorrect use may be dangerous.

- Do not eat or serve foods which smell or look abnormal and remember that they may poison household and farm animals.

- Be sure all poisons are clearly marked. This can be done by sealing with adhesive tape or using a special marker.

- When you throw away drugs or hazardous materials be sure the contents cannot be reached by children or pets.

- Warn small children not to eat or drink drugs, chemicals, plants, or berries they find, without your permission. Insist on this.

- Use cleaning fluids with adequate ventilation only, and avoid breathing vapors.

- Protect your skin and eyes when using insect poisons, weed killers, solvents, and cleaning agents. Be sure to wash thoroughly after use of such things and promptly remove contaminated clothing.

- Do not allow food or food utensils to become contaminated when using insect sprays, aerosol mists, rat poisons, weed killers, or cleaning agents.

- Do not take or give medicine in the dark. Be sure you can clearly read the label on the container.

- When measuring drugs give it your full attention. Give infants and young children drugs only as directed by your physician.

- Before measuring liquid medicine always shake the bottle thoroughly.

- Safeguard tablets which are candied, flavored or colored, since children eat them like candy.

- Do not take medicine from an unlabeled bottle—transparent tape over the label will protect it.

- Date all drug supplies when you buy them.

- Weed out the left-overs regularly from your medicine chest—especially any prescription drug that your physician ordered for a particular illness.

- Use a prescription drug only for the patient for whom the physician ordered it.

- Read all directions and caution statements on the drug label each time you plan to use it.

a letter indicating the desirability of seeing a physician.

Six departments have carried on chronic disease case finding by means of multiphasic screening programs, ordinarily in cooperation with voluntary health organizations and county medical associations. Several others have engaged in some organized case-finding services for cancer, heart disease, diabetes, or other chronic diseases as separate conditions.

Records and Statistics

Only about one-third of California's local health departments include statistical personnel on the staff. However, most departments do prepare chronic disease mortality data for use in annual reports, monthly bulletins, and talks by physicians and others. Morbidity data concerning chronic diseases are scanty. In a few instances, departments indicated that they have prepared reports concerning nursing, case finding, or other services for chronic disease. Approximately 40 departments reported that they assist hospitals and other agencies in the follow-up of cancer patients or other chronically ill patients at least through search of death certificates and other health department records. Some also provide occasional statistical services to other agencies studying chronic disease in the community.

Public Health Nursing Service

Reports from the local departments indicate that in practically all local health jurisdictions in California nursing service has become a "generalized service," with attention to the entire household, not just to the sick child or the tuberculosis suspect. The public health nurse in her home visits is usually aware of possible chronic disease in family members and offers help in making use of available screening services and other community resources. Often she encourages regular physical examinations and makes suggestions on home safety.

Public health nurses in local health department clinics are alert to the possibility of chronic disease, noting obesity and other signs which may indicate need for attention. In the

schools, the nurses often orient teachers to the possible significance of overweight and provide educational materials for school personnel and students on cancer, heart disease, diabetes, and other chronic diseases. When, in community contacts, they are asked for suggestions for meetings of various groups, many public health nurses arrange for use of educational films and other resources on chronic disease supplied by the local health department.

Two local health departments reported that they give bedside care upon request, with no restrictions. Seven other departments noted that they provide some degree of bedside nursing care for the chronically ill, beyond demonstration teaching.

Answers to questions about followup of patients showed that, in general, public health nurses were giving more attention to poliomyelitis patients than to patients who have rheumatic fever and other chronic diseases.

The majority of public health nurses in the State now have access to and utilize other specialties important to adequate care of patients with chronic illness, for example, social work, nutrition, physical and occupational therapy, rehabilitation, and psychiatry.

Social Service

Nine of the surveyed health departments include social workers as members of the staff. In addition, most departments state that they utilize social service consultation from other agencies, both those in the community and from the State health department. Wide variation was reported in resources for referral. The urban areas usually have access to many public and private agencies, and the less populated areas sometimes have only the county welfare department as a resource.

According to reports received, every health department takes some responsibility for helping chronically ill persons obtain financial, medical, rehabilitation, and casework assistance. During a multiphasic survey in one of these local health departments, the medical social worker met several times with a group of obese patients to help them discuss some of their problems in staying on diets. The social workers

supplied by the 49 departments for each major section of the questionnaire follows.

General Activities

Nineteen local health departments reported that they had carried out special projects in the chronic disease field during the past 5 years. These included multiphasic screening, special cancer studies, bedside nursing care for the chronically ill, education on health aspects of aging, and studies of the need for chronic disease hospitals, sheltered workshops, and other facilities.

Most departments maintain close liaison with the county chapters of the American Heart Association, American Cancer Society, and other voluntary health organizations active in the field of chronic disease. Usually the health officer, the director of public health nursing, the health educator, or other members of the staff serve on boards or committees of these organizations, thus aiding in the planning and development of a communitywide attack on chronic illness problems.

About two-thirds of the 49 departments indicated that they have taken leadership or joined with other organizations in promoting community services important in the control of chronic disease—for example, rehabilitation services, casework and housekeeping services, resources for the treatment of alcoholism, and tumor clinics. The health officer in one county took the leadership in getting a new wing for chronically ill patients at the county hospital, and he meets regularly with the county hospital staff to consider problems of the chronically ill.

Most departments maintain in some form current information on services for the chronically ill available in the community, for use of department staff members. As yet, however, little has been done in the way of organized staff education (in local departments) on chronic disease control, or in staff participation in planning such education.

Case-Finding Services

California's local health departments each year provide some type of clinical services to

several hundred thousand persons, including both children and adults. Many of these departments reported that they were taking additional advantage of these services for the detection of chronic disease, thus getting patients under care early and minimizing the likelihood of disability or premature death. Opportunities for such case finding have been recognized in conjunction with the usual venereal disease, maternity, child health, and preemployment clinics and as an adjunct to such established activities as tuberculosis case finding. A few departments have also carried on special chronic disease case finding.

The survey showed that 16 departments have included, or are including as part of their clinical services, one or more tests for the detection of such chronic conditions as diabetes, cancer, and heart disease. Also, in the course of their regular services, they are observing and counseling patients regarding obesity. One local department reported blood sugar screening on all venereal disease patients. Approximately 20 departments conduct maternity clinics and routinely run urine sugar tests on patients; thus, they have an opportunity in diabetes detection. Another department does a cytology test for cancer on its clinic patients and is also carrying on a cooperative program of such screening with the county hospital. Arrangements have been made in this program to include women attending obstetrics and gynecology clinics and those entering the county rehabilitation center, as well as health department staff members who wish to participate. When abnormalities are found, the patients are referred to their own physicians or to the county hospital, as appropriate, for followup diagnostic examinations and care.

According to reports received, over two-thirds of the local departments conduct some chest X-ray screening service. Although this is primarily for tuberculosis, case finding for lung cancer and heart disease is also done. In many instances, lung cancer suspects are called back for secondary films and are followed as intensively as tuberculosis suspects. Heart disease suspected from chest X-ray films generally receives less attention; only about one-third of the departments call such patients back for secondary films. Usually the patients receive only

partment staff in one county works regularly with the Aging Committee of the County Welfare Council.

Laboratory Services

For the most part, laboratory services are available only to patients coming to health department clinics for tuberculosis, rheumatic fever, or prenatal care, and for civil service employment examinations and the like. These services generally include urinalysis, blood sugar determination, hemoglobin determination, and blood counts. A few departments provide only certain clinical laboratory services, which are usually furnished by department contract with an outside clinical laboratory.

Seven health department laboratories reported that they provide a variety of clinical procedures, such as antistreptolysin titers and sedimentation rates. In 3 others, these services are provided by the department jointly with the county hospital; in 8, the laboratory work is done entirely by the county hospital, private clinical laboratories, or a combination of both.

One interesting development is a cytology screening service for cervical cancer which is operated by a county health department laboratory primarily for patients in county hospital clinics. Two other departments provide blood sugar screening for detection of diabetes. Some of the larger departments which have responsibility for rheumatic fever services utilize electrocardiograms. In a few instances, these are used also in preemployment examinations for civil service personnel. Several of the local health department laboratories have been involved in multiphasic screening programs.

Ten departments reported that they have been consulting with county medical societies and other professional groups to develop technical mechanisms for chronic disease detection.

Summary

A majority of the local health departments in California which took part in a survey of current activities in 1954 stated that they had done one or more of the following: carried out special projects in chronic disease control; maintained close liaison with voluntary organi-

zations active in this field; and either taken leadership or joined with other groups in promoting community services for the chronically ill. Although there had not been much special chronic disease case-finding effort at the time of the survey, local health departments were beginning to take advantage of their regular clinics for this purpose. Public health laboratory work is also being redirected to cope with growing problems in chronic disease. Forty of the forty-nine departments indicated that their records and statistics personnel assist hospitals and other agencies in followup of cancer or other chronically ill patients through search of death certificates and other health department records.

In the past, health department nurses have generally limited their activity in the field of bedside care to demonstration services. The intent has been to train a responsible member of the family to continue it. Recently, several factors appear to be forcing a change in this policy: smaller families and household separation of the generations; the need for close supervision in certain forms of therapy for chronic disease, such as the administration of drugs; and increasing public pressure for home care of long-term illness as an alternative to institutional care. Of all direct services to chronically ill patients, bedside nursing care now appears to be attracting the greatest attention on the part of public health administrators. Administrators of public health nursing services are actively considering the extent to which public health nurses should provide bedside nursing care in the home.

In the rural areas of the State particularly, the full range of social services needed for the care of chronic illness was often not available. However, in addition to joint work with voluntary organizations, there appears to be a trend toward closer collaboration among health departments, county hospitals, and welfare departments in meeting the needs of patients with chronic disease.

In recent years, nutritionists have given particular attention to group teaching for patients with diabetes or obesity. It also appears that nutrition information is increasingly being incorporated into the regular educational services

in another department offered individual help to chest clinic patients who were potential cardiac or cancer patients to assist them in seeking care elsewhere and in making use of resources available to them. Only a few departments provide social services directly to patients; generally, health department staff members refer patients with such problems to other community resources. Although each health department did not specifically indicate its procedure, nine noted that they follow up either with the patient or the agency to determine whether the patient received the service for which he was referred.

Nutrition Service

Only 6 of the 49 local health departments reported nutritionists as members of the staff, but most departments avail themselves of nutrition consultation from the State health department and from other local agencies.

Local health department staff members (usually the nutritionist or public health nurse) are sometimes called upon to interpret special diets prescribed by physicians for patients with diabetes, cardiovascular disease, and obesity. They also appear to be aware of the diet policies of other public agencies, such as welfare departments and county hospitals.

Only one health department reported having sponsored a course on nutrition in diabetes. However, seven departments stated that their *public health nurses are working with groups* of school children on weight control. In four agencies, nutritionists or public health nurses have been serving as group leaders with groups of obese adults. In five instances, weight-control groups have started among the staff members of the health departments themselves. Weight-control education on a group basis has progressed almost exclusively in urban areas.

Several departments have arranged for nutrition consultation to institutions caring for the chronically ill, either by local staff members or from the State health department.

In one department, the nutrition consultant conducted an education program for the nursing staff on the nutritional aspects of chronic disease, covering problems in diabetes, rheumatic fever, adult health, and obesity. One

interesting method of staff education has been the preparation of low-calorie luncheons by the nurses for the whole department, with supervision by the staff nutritionist.

Health Education

In 22 of the surveyed agencies, health educators are members of the staff.

Practically all health departments provide and distribute some chronic disease educational materials to community agencies, schools and colleges, clinics, and other appropriate groups. Several have participated in exhibits on chronic disease, for example, at county fairs. Some health departments indicated that they provide assistance to schools and colleges in planning a curriculum concerned with chronic disease.

About half of the local health departments report staff participation in providing for the community some type of group learning experiences related to chronic disease. Eleven departments have given assistance with programs on chronic disease to other agencies and community groups. For example, one department aided the county medical society with a special diabetes program designed to reach men's groups. Another worked with the local chapter of the American Cancer Society in developing a group discussion program for agricultural workers. A third assisted the county branch of the American Heart Association in *putting on a symposium on heart disease*. In another county, the health department provided assistance to the adult education division of the county schools and other groups in developing and carrying out a course on problems of aging.

In addition to the liaison that most departments maintain with county chapters of the American Cancer Society, one department reported that it carries out regular joint planning of educational activities with the local society. These include inservice education for public health nurses serving county schools, in the use of approved cancer education kits as teacher resources. Another department reports having discussed cancer and some other chronic diseases at joint staff meetings with the county schools curriculum committee. The health de-

One of several integrated studies of physiological fluoride effects, this series of tests explored the toxic effects in animals as a basis for studies in man. The tests demonstrated that an appreciable amount of fluoride is necessary to produce deleterious effects.

Acute and Subacute Toxicity Studies of Sodium Fluoride in Animals

By NICHOLAS C. LEONE, M.D., ERVING F. GEEVER, M.D., and NEIL C. MORAN, M.D.

CURRENT knowledge of the dosage of fluoride required to produce toxic effects in man is derived principally from suicidal or accidental poisonings (1-5). Since the exact doses ingested and absorbed are unknown, interpretation of the relationship between clinico-pathological findings and dosage is difficult. The lack of reliable methods for determining minute blood fluoride levels adds to the difficulty of evaluation.

With the more widespread use of fluorides in industry, in agriculture, and in the home, there is need for additional evaluation of acute fluoride effects. Whereas some information is available concerning chronic toxicity, there is

less concerning the acute toxic effects in man and animals.

The present study was undertaken to obtain data on the acute and subacute physiological and pathological effects of intravenously and orally administered sodium fluoride in animals. It was also undertaken to determine the safe limits of intravenous administration as an aid to the study of fluoride excretion in man.

Methods

Two types of animals, dogs and mice, were used in the experiments.

The 27 dogs tested were unanesthetized mongrels of both sexes, weighing from 7 to 10 kilograms. For convenience the dogs were separated into five groups as follows:

Group 1. Five dogs were used for the determination of the acute lethal dose by continuous infusion to the point of death, using a calibrated infusion pump.

Group 2. Nine animals were given sodium fluoride in selected fractions of the acute lethal dose (with the same technique and infusion rate as in group 1) and observed for varying periods.

Group 3. Two dogs were given daily intravenous injections of sodium fluoride for 23 days.

The authors are all with the National Institutes of Health, Public Health Service. Dr. Leone is chief of Medical Investigations and Dr. Geever is pathology consultant with the National Institute of Dental Research. Dr. Moran is head of the Pharmacodynamics Section of the Laboratory of Chemical Pharmacology, National Heart Institute.

Technical assistance was given by William M. Butler, Jr., M.S., and James S. Watts, B.S., of the Laboratory of Chemical Pharmacology, and Patricia B. Geiser, M.S., Public Health Service Nurse Officer with the National Institute of Dental Research.

of health departments in California, with use being made of films, printed materials, and demonstrations.

This survey, in addition to bringing in the information, served an immediate educational function. It focused the attention of hundreds of public health workers throughout the State on things that were being done and things that could be done for chronic disease control.

The information compiled and presented in this report is that furnished to the consultants of the California State Department of Public

Health by the health officers and members of their staffs. It indicates, from an overall viewpoint, that health department services and activities for chronic disease control in California, while not extensive, are increasing. Although no one department is carrying out a comprehensive program for the prevention and control of chronic disease, and in some agencies little or no attention is being given to this field, the trend seems clear—a gradual reorientation of public health services to meet the needs of the chronically ill.

An Important Date

Each month your health department and many hospitals, laboratories, schools, clinics, and homes receive a copy of **PUBLIC HEALTH REPORTS**, mailed to arrive on the 20th, or even earlier, depending upon geographic location of the subscriber.

Its pages carry timely research reports, analyses of current trends, new methods, concepts, and ideas, and topical reviews for the busy scientist, teacher, or public health worker. Capsule coverage of important public health meetings, like those of the American Public Health Association, help the PHR reader.

You can have your personal copy promptly. Use the subscription blank on the inside back cover. Let the 20th of each month be an important date for you, too.

Scheduled for early publication

Special Section on Food and Drugs
Variations in Mortality from Heart Disease
Patient Care in Proprietary Nursing Homes
Biology of Northern Mosquitoes
Microbiological Laboratory Safety
Enigmas in Gonorrhea

Public Health Reports

Nile blue were made on renal tissue from 7 controls and 11 fluoride-treated dogs from groups 1, 2 and 3.

For mice the oral and intravenous lethal doses (LD_{50}) were determined by using fasted, male, white mice of uniform weight (10 grams). Each dose level was evaluated in groups of 10 or more mice. The LD_{50} was calculated by the method of Litchfield and Wilcoxon (7). The arbitrary end point was 24 hours after administration.

Physiological Effects in Dogs

Group 1

Four dogs were given sodium fluoride by continuous infusion at a rate of 5.4 mg. of fluoride ion per minute to death. The mean acute lethal

dose was 36.0 ± 0.5 mg./kg. (tables 1 and 2). An additional animal was infused at a rate of 1.1 mg. per minute to a lethal dose of 31 mg./kg. but is not included in the calculation of the mean acute lethal dose because of the difference in infusion rate.

No significant change in arterial blood pressure occurred until an average dose of 15 mg./kg. was reached. Beyond this point there was a moderate decrease in pulse pressure. From 20 to 30 mg./kg. there was a moderate fall in systolic and diastolic pressure, after which a rapid, progressive fall of blood pressure occurred (fig. 1).

Little change in mean heart rate was noted at low doses; however, after 20 mg./kg. had been given, there was a progressive decline in rate to zero at death (fig. 1).

Consistent electrocardiographic changes did

¹ Doses expressed as fluoride ion. ² Mean of 4 dogs. ³ Death occurred during continuous infusion.
⁴ Single intravenous injection given daily for 23 days. S=Sacrificed.

Group 4. Four animals were given sodium fluoride in single doses by mouth.

Group 5. Seven untreated dogs were sacrificed by exsanguination to provide normal control material for the pathological anatomy studies.

Under local anesthesia, the femoral artery and vein of the dogs in groups 1 and 2 were cannulated for recording arterial pressure and for intravenous infusion. Blood pressure was recorded with an Anderson glass capsule manometer (6). Respiratory rates and electrocardiograms were recorded by routine methods. In all groups, pupil size and reactivity, tendon reflexes, emesis, defecation, urination, and other significant behavioral and neurological changes in the animals were also observed. In groups 1, 2, and 4, blood was taken before and after administration of sodium fluoride for the determination of serum calcium.

The term "acute lethal dose," as used throughout, refers to that dose at which death occurred as the result of continuous intravenous infusion (group 1). The term "subacute lethal dose" arbitrarily applies to that dose of fluoride causing death one or more hours following administration (group 2).

A sterile, pyrogen-free solution of sodium fluoride (10 mg. of F ion per ml.) was used for intravenous administration; sodium fluoride powder was used for oral administration.

All doses are expressed in terms of the fluoride ion.

Necropsy was performed as soon after death as possible, in most instances immediately. Animals that did not die as a direct result of administered fluorides were sacrificed by exsanguination following sodium pentobarbital anesthesia. Necropsy was not performed on the animals that received fluoride by mouth. Tissues were fixed in 10 percent formalin for microscopic examination, and routine methods of tissue preparation, paraffin embedding, and hematoxylin and eosin stains were employed. Special fat stains using oil red O-hemalum and

VF denotes ventricular fibrillation.

not appear until a mean dose of 30.6 mg./kg. was reached, when there was conversion in every dog to atrioventricular nodal or ventricular rhythm. The terminal cardiac event was either ventricular fibrillation or asystole (table 2). Occasional changes in the amplitude and direction of the T waves and S-T segments were noted before loss of sinus rhythm but were not consistent. Durations of PR, QRS, and QT intervals did not change until abnormal rhythms occurred. Figure 2 illustrates the electrocardiographic tracings of a representative experiment.

On necropsy the hearts were usually found in systolic contracture. When arrested in diastole, slight mechanical stimulation of the heart induced contracture.

Average respiratory rates did not change appreciably until a dose of about 20 mg./kg. was reached, when an increase occurred. From 30 mg./kg. to the lethal dose, a progressive depression of rate was observed (fig. 1) as also was amplitude. In most of the animals there were frequent short periods of tachypnea, often occurring during the phase of central nervous system depression.

Depression of the central nervous system progressing to coma appeared in all group 1 animals at doses of from 23 to 31 mg./kg. Pupil size and reflex response to light were unaffected until moderately severe central depression developed. At that stage dilation and hypoactive reflexes were noted. Terminally, maximal dilation and areflexia of the pupils occurred. The corneal reflex persisted until the period immediately prior to death. Depression of tendon reflexes paralleled the central depression. Convulsions were not observed in the animals of this group in which the infusion rate was fast. However, in the one case with a slower infusion rate, a stage of neuromuscular hyperexcitability was prominent in the dose range of from 22 to 25 mg./kg. Characteristic of this phase were hyperactive tendon reflexes with clonus, tonic convulsions, and muscle fasciculations. This stage merged into the comatose state described in other animals.

Emesis and defecation were consistent effects with a mean emetic dose of 19.7 ± 0.8 mg./kg. (table 2). Defecation usually occurred shortly before or immediately after emesis.

Group 2

The dogs in group 2 were infused at the rate of 5.4 mg. per minute. The infusions were stopped at arbitrarily chosen fractions of the acute lethal dose of group 1 (15, 20, 25 mg./kg.), and the animals were observed until death or sacrifice.

Three dogs which received 25 mg./kg. of fluoride died within 1 to 31 hours after the end of the infusion. One of the two dogs given 20 mg./kg. died at 36 hours, while the other survived until sacrificed at 7 days. None of the four animals administered 15 mg./kg. died as a result of the fluoride. An approximate subacute lethal dose 50 (LD_{50}) of 20 mg./kg., therefore, might be assigned to fluoride when given by this method of administration. Table 1 summarizes the results in this group.

Up to the point where the infusions were stopped in the group 2 animals, the cardiovascular and respiratory effects were similar to those of group 1 (fig. 1). There were no consistent electrocardiographic changes in these animals although recordings were not obtained in the period immediately preceding death in those animals which succumbed to the fluoride.

Depression of the central nervous system began before completion of the infusion in all three dogs given 25 mg./kg. and deepened progressively until death. Similar depression was observed in the animal that died as a result of 20 mg./kg. of fluoride. All of the other group 2 animals passed through a short stage of reduced activity, but no severe depression was observed.

Emesis occurred in all of the animals that received 20 or 25 mg./kg. Two of the four dogs receiving 15 mg./kg. of fluoride vomited about 30 minutes after cessation of the infusion.

Group 3

Group 3 consisted of two dogs given fluoride by daily intravenous injections of 5 mg./kg. for 23 days. Blood pressure and respiratory rates were not recorded. The animals remained in good condition with no evidence of toxic effects or weight loss. Electrocardiographs remained normal. The results are summarized in table 1.

Figure 2. Electrocardiograph tracings (standard limb lead II) show the progressive effects of increasing doses of sodium fluoride on the heart of an unanesthetized dog. The rate of intravenous infusion was 5.4 milligrams of fluoride ion per minute in a 9.2 kilogram dog.

Control

28.6 MG/KG

17.6 MG/KG

31.8 MG/KG

23.4 MG/KG

34.6 MG/KG

Microscopically, all animals that died after fluoride administration and one surviving until sacrificed at 36 hours showed generalized hyperemia and acute focal hemorrhages. All other animals showed some focal hyperemia and focal hemorrhages, but the conditions were no more severe than those in the control group.

Although special attention was given to brain, heart, liver, kidneys, lungs, gastrointestinal tract, and bone marrow, no other histological evidence of cellular injury could be found in any animal. Differences in fat concentration were found, but variations were as great among the controls as among the animals exposed to fluoride. The fat appeared to be liberated from the cytoplasm of the tubular epithelium, particularly along the cortico-medullary junction.

Incidental findings, common to the treated and the control dogs, included roundworm and tapeworm infestation of the intestinal tract and microscopic acute and chronic nonspecific inflammation of the lungs, kidneys, liver, and, less often, of the myocardium.

Discussion

On the basis of the present study several points stand out in regard to the acute toxicity of sodium fluoride in dogs.

First, the doses of intravenously administered fluoride required to produce acute toxic effects in animals are high, and there is no evidence of cumulative effects on daily administration of sublethal doses for a period of 3 weeks.

Second, the more uniform effects with a constant rate of intravenous infusion of sodium fluoride are in contrast to the more erratic results and difficulty in producing toxic effects with oral administration.

Third, the physiological effects and pathological changes seen in dogs given toxic doses of fluoride resemble those reported in human fluoride poisoning (1-4).

The greater uniformity of results seen in groups 1 and 2 on intravenous administration is most evident in the relatively precise doses at which the various physiological effects occur. In contrast, the erratic results observed when fluoride is given to dogs by mouth are largely

due to the loss of undetermined amounts of the administered dose through vomiting.

Diarrhea and bloody stools were observed in some animals in which death was delayed from 1 to 36 hours. Similar findings have been reported in human cases (1, 3, 4).

The vasodepressor action of fluoride seen in this study has been demonstrated by Greenwood and associates (10). It probably is due to a combined depression of the vasomotor centers of the brain and of the vascular smooth muscle. The cardiac arrhythmias, resembling those resulting from high serum potassium, are probably caused by enhanced sensitivity of the myocardium to potassium, secondary to decreased serum calcium concentration. The terminal systolic contracture is of particular interest in view of Loewi's recent observations of a positive inotropic effect of sodium fluoride on the depressed frog heart (11). He suggests this action is caused by the formation of a complex of fluoride, a cellular constituent and calcium, and that this complex restores the cellular membrane excitability to normal. However, no conclusive evidence is available to suggest a comparable action in mammalian hearts.

The central nervous system and neuromuscular effects of sodium fluoride may be related to two actions: one, a reduction of ionizable calcium through a fluoride binding effect, resulting in a state of neuromuscular hyperexcitability, that is hypocalcemic tetany, and, second, a depression of the central nervous system as a possible result of enzyme inhibition (12).

Routine pathological studies did not demonstrate a specific mechanism of death in experimental fluoride exposure, but at the levels used in this study, and with the short interval to death in many instances, direct toxic cellular effects cannot be ruled out despite the lack of histological evidence of injury. The gross and microscopic pathological examination showed only generalized congestion and acute focal hemorrhages. Similar changes in man and animals have been described for deaths due to fluoride poisoning (1, 4, 13, 14). These changes are interpreted as resulting from injury to vascular endothelium.

Fatty changes have been described in the

Group 4

The four animals in group 4 were each given a single dose of sodium fluoride by mouth in powder form. One received the compound mixed in food and the others in gelatin capsules. Doses of 38, 81, 260, and 3,100 mg./kg. of fluoride were given. The main effects observed were vomiting and frequent defecation. In one case (3,100 mg./kg.) the vomitus was grossly bloody and the animal was mildly stuporous for a short period. In every dog in this group there was apparently complete recovery in 18 to 24 hours.

Physiological Effects in Mice

The oral LD_{50} with standard error was 46.0 ± 1.6 mg./kg. as compared with an intravenous LD_{50} of 23.0 ± 0.9 mg./kg. (table 3). Mice dying within 2 hours after injection showed successively cyanosis, dilatation of ear vessels, depression of respiration, tremors, clonic convulsions, paralysis of the hind legs, loss of righting reflex, depression, respiratory arrest, and death. Those with longer survival periods (2 to 24 hours) went through similar, but less severe, stages, progressing to a long terminal depression.

Serum Calcium and Blood Clotting

The effects of fluoride on serum calcium were determined on 11 dogs (table 4). Whole blood was drawn for serum calcium determinations prior to infusion and again immediately before death in the group 1 animals. In the group 2 animals, blood was drawn prior to and at the end of infusion. Blood was drawn from 1 animal in group 4 approximately 1 hour after administration. There was a slight drop in serum calcium in 9 of 11 animals. This finding has been reported by others (3, 8, 9).

Although no clotting-time determinations were done, soft, friable, poorly contracted clots were observed in blood samples drawn after fluoride administration.

Pathological Anatomy of Dogs

The only gross pathological changes noted in dogs were generalized hyperemia in the animals

that died after fluoride administration, whether acute or delayed and, in addition, focal hemorrhages in those dogs that died from 18 to 36 hours after fluoride administration.

The vasodepressor action of fluoride seen in this study has been demonstrated by Greenwood and associates (10). It probably is due to a combined depression of the vasomotor centers of the brain and of the vascular smooth muscle. The cardiac arrhythmias, resembling those resulting from high serum potassium, are probably caused by enhanced sensitivity of the myocardium to potassium, secondary to decreased serum calcium concentration. The terminal systolic contracture is of particular interest in view of Loewi's recent observations of a positive inotropic effect of sodium fluoride on the depressed frog heart (11). He suggests this action is caused by the formation of a complex of fluoride, a cellular constituent and calcium, and that this complex restores the cellular membrane excitability to normal. However, no conclusive evidence is available to suggest a comparable action in mammalian hearts.

The central nervous system and neuromuscular effects of sodium fluoride may be related to two actions: one, a reduction of ionizable calcium through a fluoride binding effect, resulting in a state of neuromuscular hyperexcitability, that is hypocalcemic tetany, and, second, a depression of the central nervous system as a possible result of enzyme inhibition (12).

Routine pathological studies did not demonstrate a specific mechanism of death in experimental fluoride exposure, but at the levels used in this study, and with the short interval to death in many instances, direct toxic cellular effects cannot be ruled out despite the lack of histological evidence of injury. The gross and microscopic pathological examination showed only generalized congestion and acute focal hemorrhages. Similar changes in man and animals have been described for deaths due to fluoride poisoning (1, 4, 13, 14). These changes are interpreted as resulting from injury to vascular endothelium.

Fatty changes have been described in the

tubular epithelium of rat kidneys following prolonged administration of sodium fluoride (15). In our dogs, shift of renal fat was noted, but no consistent pattern could be found on comparison with the normal controls.

Reviewing the results of this study, it is interesting to compare the findings in animals with human cases of fluoride poisoning (1-4). Outstanding is the study of Lidbeck, Hill, and Beeman, who reported a mass accidental poisoning of 263 persons with 47 fatalities (1). They described respiratory and cardiovascular depression as a common finding in addition to a number of other manifestations also observed in the present study. An example is: "General collapse developed in most instances but at variable periods of time, apparently depending upon the concentration of the poison. This was characterized by pallor, weakness, absent or thready pulse, shallow, unlabored respiration, weak heart tones, wet cold skin, cyanosis, and equally dilated pupils. When this picture was pronounced, death almost invariably occurred." This description closely follows the findings in our animals receiving a fatal dose of fluoride.

In the present study and the clinical cases described by Lidbeck and associates, convulsions were not regularly observed. However, the carpopedal spasm and spasm of the extremities, described by these authors in a few patients who recovered or where death was delayed, resembled the neuromuscular hyperexcitability seen in one dog in the present study. These effects may be manifestations of hypocalcemic tetany. Generalized convulsions which have been described by others could be on the basis of cerebral anoxia or severe hypocalcemia (2).

On a practical basis, the data from this study may be of value in the evaluation and treatment of cases of acute fluoride poisoning in man. For instance, electrocardiographic demonstration of a cardiac arrhythmia in the absence of known heart disease would suggest that about three-quarters of the acute lethal dose had been absorbed and would imply poor prognosis. Central nervous system depression to a marked degree might also denote the absorption of more than half of a lethal dose.

The intravenous lethal dose of fluoride determined in the present study agrees well with

those previously reported if differences in injection rates and in species are considered (10, 16, 17).

This information, establishing the relatively high dosage of fluoride required to produce acute toxic effects in animals, suggests that small intravenous doses may be used with safety for human studies. The absence of toxic effects in dogs given 5 mg./kg. of fluoride intravenously daily for 3 weeks also suggests a considerable margin of safety and an apparent absence of accumulative toxic effects in this period of time.

Summary

In this limited study, designed to evaluate the acute toxic effects of sodium fluoride in dogs and mice, it was demonstrated that:

1. The mean acute lethal dose of sodium fluoride in unanesthetized dogs infused to death by continuous intravenous infusion at the rate of 5.4 mg. of fluoride ion per minute was 36.0 ± 0.5 mg./kg. The principal effects were progressive depression of blood pressure, heart rate, and central nervous system with vomiting and defecation, all occurring with the administration of approximately 20 mg./kg. At a mean dose of 30.6 mg./kg. there was a depression of respiratory rate and a conversion to atrioventricular nodal or ventricular rhythm with terminal ventricular fibrillation or asystole.

2. In a group of dogs infused intravenously with selected fractions of the acute lethal dose, an approximate LD_{50} was estimated to be 20 mg./kg. The major effects observed in this group were vomiting, defecation, and central nervous system depression. In the fatal cases death occurred in 1 to 36 hours.

3. In a group of dogs given 5 mg./kg. intravenous injections daily for 23 consecutive days, no toxic effects were observed.

4. In dogs, single doses up to 3,100 mg./kg. of fluoride by mouth produced only vomiting, defecation, and transient moderate depression.

5. The intravenous LD_{50} in mice was 23.0 ± 0.9 mg./kg. and the oral LD_{50} , 46.0 ± 1.6 mg./kg.

6. A slight drop in serum calcium followed the infusion of fluoride in most dogs in which serum calcium was determined.

7. The pathological findings in those animals which died directly as a result of sodium fluoride administration consisted of generalized hyperemia and acute focal hemorrhages.

Inventory of Water Needs

At least one of every four large urban areas have reported they need additional water supplies to meet anticipated municipal and industrial growth, according to a nationwide inventory taken by the Water Supply and Water Pollution Control Program of the Public Health Service.

Of 1,532 community water facilities, 367 serving a population of nearly 20 million need additional water supplies. About one-fourth of the water supply facilities need additional distribution systems, partly because of the growing practice among municipalities to provide water service to suburban areas. More than half of the facilities need improvement or enlargement.

The inventory covered all facilities serving 10,000 people or more and a 40-percent sample of facilities serving between 5,000 and 10,000 people. It lists population served, source of supply, treatment provided, capacity, storage, and the improvements which local officials consider necessary to maintain satisfactory service. Additional details are available from the Water Supply and Water Pollution Control Program, Public Health Service, Washington 25, D. C.

Accident Prevention In Sanitation

By EDGAR F. SEAGLE, M.S.P.H.

THE ESSENTIAL points of this paper have been used to introduce to local health department personnel in North Carolina the close relationship between good sanitation practice and accident prevention. This concept of sanitation, though obvious in principle, seems to be difficult for many health workers to visualize in specific terms. The following examples, presented at State and local health staff conferences, appear to have improved acceptance and understanding of this concept and to have advanced and encouraged its many applications, with good results for sanitation all around.

A change of concepts has been characteristic of the progress of sanitation services. For example, not too many years ago sanitarians dressed like policemen and worked principally on the basis of enforcing laws which neither they nor their clients thoroughly understood. Sanitarians today dress like teachers or salesmen, and they work primarily to promote sanitation on its own merits, with a foundation of public acceptance, understanding, and approval. The word sanitation itself illustrates how concepts have changed. For many years, it has been associated primarily with cleanliness. But its original meaning was the protection of health; and that original meaning is restored to the extent that sanitarians broaden their responsibility and understanding.

Accident prevention is one program for protecting health which forces sanitarians to look

beyond details of neatness and cleanliness toward the true objectives of their work. At the same time, accident prevention enjoys much broader public understanding and acceptance than the processes of preventing contamination of food by invisible microbes. It is not only within full ken of human experience, but it also appeals directly to self-interest. Everyone is certain to be more concerned with a possible accident to themselves than with the uncertain and indirect effects of his habits on others.

Control of Hazards

To illustrate how accident prevention can play an important role in the improvement of sanitation, consider first the food handler working in the kitchen of a restaurant. If this person has an open cut or wound on his hand while preparing certain foods, the potential for contaminating this food with infectious bacteria is certainly high. Of course, if this person has been well schooled in proper food handling, he would not work with an open cut, but how many are so trained? The safe approach is to prevent such an accidental cut if possible. In one instance, every time a food handler reached for a certain pan he either scratched or cut his hand on a sharp edge of metal on the side of the storage cabinet. If this environmental hazard had been corrected, the food handler would not have had so many cuts. At the same time, his potential of food contamination would have been less. The manager might be induced to correct such conditions more readily if the element of personal pain and suffering, as well as liability for workman's compensation, had been discussed along with the food infection hazard. This approach also gives a client the feeling that you are interested in him personally and helps to secure cooperation.

Sanitarians have long been concerned with the cleanliness of floor and wall surfaces. To maintain cleanliness they should be made of smooth, washable, nonabsorbent material, free from cracks, crevices, and open joints. Such a surface certainly is a poor place for germs to

Mr. Seagle is sanitation consultant with the accident prevention section of the division of epidemiology, North Carolina State Board of Health, Raleigh, N. C. This accident prevention project is sponsored by the W. K. Kellogg Foundation.

take a foothold. It also, however, contributes to safe walking and movement on the premises. The fact that floor surfaces, if properly constructed, contribute not only to cleanliness but to safety is another example of how accident prevention can strengthen a sanitation program. It also illustrates that sanitarians have been engaged in accident prevention often without directly realizing what they have achieved.

Restaurant and meat market regulations usually require adequate lighting and ventilation. Here again these regulations were primarily set up in the interest of cleanliness; that is, if you can see dirt, you can clean it up. Another important advantage in good lighting though is to reduce accidents. Poorly lit cellars or stairs need no comment: Their high potential as a source of falls resulting in disabilities and death is too well known. Good lighting is certainly needed to see that equipment is effectively washed and cleaned. However, good lighting at the cutting, mixing, or grinding table in the kitchen may prevent a slash to a finger or hand. Many a hand is caught in a piece of equipment because the moving parts are not clearly seen in a dim light. Here again, the accident prevention concept for the operator or foodhandler is a strong supplement to sanitation.

Garbage cans also may figure in preventing accidents. For example, many garbage cans of food-handling establishments sit on back platforms, to be emptied daily. When there are enough cans, there is less spilling refuse and other wastes and the walking area is more likely to be dry and clear. However, if garbage cans overflow, meat scraps, bones, rubbish, offal, filth and other wastes are strewn over the back platforms and eventually are kicked or carried into the kitchen. Articles of this kind provide a slippery underfooting and may provoke a bad spill or fall as much as a broom or other heavy litter in the walking area. Therefore, walkways clear of garbage discourage breeding of flies, rodents, and germs, but also discourage the chances of accidental falls.

It is recommended that merchandise in the storage room be stored on elevated platforms to facilitate cleaning. If this recommendation is carried out, things are certain to be more in order than if they are strewn on the floor at

random. Here also, the possibility of tripping and falling is reduced. Again, neatness and accident prevention join in the common cause of sanitation.

Farm Sanitation

Examples of sanitation improvement by eliminating accident producing environmental conditions can be found also on farms and in dairies. Uncovered holes or slick surfaces on graded levels around the barn may result in cows slipping and injuring their udders. Such injuries in turn may produce mastitis. Mastitis means not only an economic loss to the farmer but may also mean a possible danger of infection in the milk. However, an employee or the farmer himself may fall and break a leg in these same danger spots. Therefore, if farm sanitation work is done with an eye towards protecting the farmer as well as the cow from accident, both may benefit. Such hazards are typified also by discarded pit privies. If these are effectively filled in, there is less possibility of spreading disease; however, the fill also reduces the chances for an accident. Discarded wells also should be filled in or securely covered, for similar reasons.

As to insect and rodent control, the North Carolina State Board of Health is pursuing a project which although designed primarily to prevent mosquito breeding also prevents many home accidents. This project is that of inspecting every home and farm pond and stressing that all tree stumps and other obstructions be completely cleared from the pond bed. The regulation calls only for these stumps to be a certain number of inches below the fluctuating water level. However, sanitarians strongly recommend complete clearing of the pond bed. They then accomplish both the primary purpose and also eliminate the chance that swimmers diving in the pond may hit their heads on these obstructions, as well as the threat to boats on the larger ponds. If a farmer is reluctant to believe that these stumps have any important relation to mosquito breeding, he may be more readily convinced that some member of his family can be seriously injured or killed if the stumps remain.

There are many other examples of the close relationship between accident prevention and other phases of sanitation.

In North Carolina, studies have shown that there were 825 accidental deaths in 1954 on the farm and in the home. This is a rate of approximately 2 deaths per day. It has been estimated that for each of these fatal accidents, there are 150 accidental injuries resulting in disability for 24 hours or longer, and 4 of these are permanent disabilities. Any accident prevention activity should be preceded by an in-service training program for sanitarians and a

check list of home hazards agreed upon and approved. Armed with this knowledge, the sanitarian could then discuss such situations on the spot and make recommendations for the most practical means of elimination or correction. Such a program may be used by all categories of public health personnel who visit the public in their daily duties. Accidents are unquestionably one of the major health problems. Sanitation personnel have a great opportunity to combine accident prevention activities with their existing programs. Such a forceful combination would add even greater satisfaction to their present valuable work.

Galactosemia Cause Found

The cause of galactosemia, also known as galactose diabetes, an often fatal metabolic disease of children, has been discovered by scientists of the National Institute of Arthritis and Metabolic Diseases, Public Health Service. It was reported in official announcements on March 12, 1956.

This disease ordinarily appears within a few days after birth. The infant suffering from galactosemia is unable to utilize or even tolerate milk in any form. Lactose, often called milk sugar, contains another sugar, galactose. This substance cannot be handled by the child's system if he has galactosemia.

Drs. Herman M. Kalckar, Elizabeth P. Anderson, and Kurt J. Isselbacher at the National Institutes of Health discovered a hitherto unknown enzyme in normal red blood cells, which they call P-Gal transferase. This enzyme, they found, is necessary to complete conversion in the body of galactose into glucose, the common sugar of the blood.

Diagnosis of galactosemia is difficult because the symptoms are similar to those of other disorders. Diarrhea, lack of appetite, loss of weight, and jaundice appear in the earlier stages. In later stages, the disease leads to cirrhosis of the liver, mental retardation, blindness due to cataract, and death.

Early recognition of galactosemia is highly important, since the disease progresses rapidly, leaving serious irreversible changes. When diagnosed in an early stage, treatment is simple. The affected child, placed promptly on a milk-free diet, will grow and develop normally.

The discovery of P-Gal transferase promises to provide a rather simple diagnostic test, making earlier life-saving treatment possible. It also points the way to exploration of the possibility that impairment of galactose metabolism may be a factor in other disorders of unknown origin.

The model poultry ordinance as it now stands deals only with the general enforcement and sanitary provisions. A part dealing with inspection is to come.

Development of a Poultry Ordinance

By JOE W. ATKINSON, D.V.M.

THE Public Health Service has developed a model poultry ordinance for voluntary consideration by State and local agencies which are conducting or planning inspection and sanitation activities regulating the processing, storage, transportation, and sale of poultry and poultry products. Why and how was the ordinance developed? What is its potential value?

Background

The poultry industry has doubled in size since 1940. In 1953, it was the third largest source of gross farm income, representing 12.1 percent of the total. The value of poultry and poultry products, including eggs, was almost \$4 billion at the farm level and \$6 billion at the retail level. Per capita consumption of poultry meat reached 34.4 pounds.

A radical change in buying habits and merchandising methods has accompanied this tremendous growth. The consumer seldom sees the live bird to evaluate its health. Processing has progressed from on-the-spot slaughter, observed by the customer, to production line methods. The product may be stored for ex-

tended periods, shipped long distances, and consumed far from the point of origin. This mass processing and distribution has presented new problems in meeting standards of consumer expectancy and of public health.

Diseased Poultry

Noteworthy progress has been made in the prevention and treatment of poultry diseases, yet a substantial number of diseased birds are marketed. Entire flocks may be sent to slaughter in an attempt at salvage when disease outbreaks appear. The production of large commercial flocks in crowded facilities and concentrated areas heighten the possibility of the dissemination of disease, as shown currently by the high rate of respiratory diseases in areas of concentrated broiler production. The number of pounds of poultry condemned by the Poultry Inspection Branch, Department of Agriculture, as unfit for human consumption ranged from 4,075,121 in 1951 to 6,960,529 in 1954 (table 1).

In the poultry processing industry, as in other industries, the advent of mass production operations has brought increased occupational health problems. During recent years, scattered outbreaks of psittacosis among employees of poultry-processing establishments emphasized the necessity for adequate ante-mortem and post-mortem inspection of poultry, high standards of sanitation, and special protective measures in reducing possibilities of employees' becoming infected while at work. A transmissible disease may assume increased public

health significance through a previously unknown strain of the infective organism, through the adaptation of a known strain into a form more highly virulent to man, or through certain conditions which enhance the transmissibility of the disease from the animal host to man or from man to animal (1).

Insanitary Conditions

The 1950 annual report of the Food and Drug Administration stated: "In the meat and poultry projects, major attention from a filth standpoint was given to poultry that was decomposed or contaminated by fecal matter in washing and scalding tanks."

Quoting from the report for 1951: "Poultry ranks third in the number of filth and decomposition charges. When meat prices increased, many inexperienced operators entered the field of poultry production. More than three times as many seizures of unfit birds were made as in the previous year. The main causes of com-

plaints were contamination by fecal matter, preparation under unsanitary conditions and diseased, improperly dressed birds."

And the 1952 report said: "There was continued pressure to improve the sanitary handling of poultry in dressing plants and eliminate traffic in diseased birds. Plants visited ranged from "pot scalders" to assembly line establishments dressing 600,00 pounds of broilers in a 24-hour day. Conditions varied from excellent to repulsive, regardless of size or type of equipment. About 200,000 pounds were seized."

Foodborne Outbreaks

The types of *Salmonella* that frequently cause foodborne illness in man are commonly found in poultry. Furthermore, although in many instances the poultry probably is not the original source of the organisms, processed poultry, poultry products, or poultry dishes, such as pies, salads, "dinners," are frequently contaminated with Arizona paracolon, staphy-

lococci, or other organisms associated with food-borne outbreaks.

Feig's analysis of food infections and food poisonings in man shows poultry to be one of the common vehicles incriminated in food-borne outbreaks caused by food other than milk (2). Of such foodborne outbreaks reported by the States to the Public Health Service, the percentage of cases associated with poultry and poultry dishes has been relatively high since 1945 (table 2).

Dauer stated in his summary of disease outbreaks (3): "Poultry and eggs were far more important than milk or water as sources or vehicles of infection. . . . These reports very clearly indicate that fowls and eggs constitute a large reservoir of infection, and they emphasize the need for more effective methods to prevent transmission of infection to man." In the 1953 summary (4), Dauer and Sylvester reported that in one-third of the outbreaks caused by *Salmonella*, chicken or turkey was found to be the vehicle of infection. Of the total of 209 waterborne and foodborne outbreaks, involving 10,730 cases reported by the States in 1953, 65 outbreaks (31.1 percent), involving 4,696 of the cases (43.7 percent), were associated with poultry. These percentages are based on reports from the National Office of Vital Statistics.

In foodborne outbreaks, epidemiological studies are often incomplete. Yet, it has been shown from the number of cases reported that, unless adequate preventive measures are continuously effected, poultry or poultry products may serve as a source or vehicle of infection (5-7). For this as well as for other reasons, health authorities have recognized the need for poultry inspection services and for adequate sanitation and refrigeration in the processing and subsequent handling of poultry and poultry products (8, 9).

State and Local Problems

The Food and Drug Administration regularly examines poultry shipped interstate and inspects the plants of origin. Furthermore, approximately 25 percent of the poultry processed in this country originates in establishments voluntarily operating under the poultry

inspection service of the Department of Agriculture. Nevertheless, it is estimated that approximately 70 percent of the poultry processed is not inspected by either the FDA or the Department of Agriculture. This is due, in part, to limitations on funds available for the purpose under the FDA programs and to the fact that inspection by the Department of Agriculture is not mandatory for all poultry shipped interstate. Furthermore, more than half of the poultry consumed in the United States is sold within the States in which it is processed and is not necessarily subject to these Federal programs.

Consequently, extensive problems remain for State or local control. Some jurisdictions have recently revised or adopted regulations. In a few instances, the mere variety of proposed regulations has threatened the industry with trade barriers. Other jurisdictions are aware of the need for uniform action and have requested guidance, including a suggested ordinance, from the Public Health Service. Added to these requests from health officials were the recommendations in 1952 of the Conference of State and Territorial Health Officers and of the United States Livestock Sanitary Association that a model ordinance be developed to aid the States in strengthening their poultry sanita-

Table 2. Number and percentage of cases associated with poultry and poultry dishes from total of cases in foodborne outbreaks (attributed to all foods other than milk and milk products)¹

¹ As reported by the States to the Public Health Service.

tion programs. That same year the Institute of American Poultry Industries offered to assist the Public Health Service in the development of such an ordinance.

The Ordinance

The Public Health Service poultry ordinance has been developed as a joint project of the Milk and Food Program, Division of Sanitary Engineering Services, in Washington and the Veterinary Section, Epidemiology Branch, Communicable Disease Center, in Atlanta.

Field studies were conducted, and existing State and local regulations and programs were reviewed. Following completion of a first study draft of the general enforcement and sanitation provisions of the ordinance, a Public Health-Poultry Industry Liaison Committee has acted as an advisory group in its further development. This liaison committee is composed of seven members from the Public Health Service and State and municipal health departments and an equal number of members from the Institute of American Poultry Industries. The committee outlined three broad objectives:

1. Poultry should be handled only in clean establishments in a clean manner.

2. Only wholesome poultry should be offered to the consumer.

3. All trade barriers not based on sound public health principles should be avoided.

A study draft of the general enforcement and sanitation provisions of the ordinance was distributed for review and comment to major organizations of the poultry industry, to State and local agencies, and to many National organizations composed of health officials or related professional personnel.

Representatives of the Department of Agriculture, the Food and Drug Administration, and the Department of Defense were consulted at frequent intervals. They reviewed the study drafts and offered many helpful suggestions for revisions. Substantial agreement was reached on all general enforcement and sanitation requirements of the ordinance, and they were published in April 1955 as the Poultry Ordinance, 1955 edition (Public Health Service Publication No. 444).

Provisions dealing with ante-mortem and post-mortem inspection of poultry have been developed in draft form and submitted in a similar manner to the industry and to many interested agencies and groups for review and comment. These provisions are to be completed during this fiscal year.

Basis of Provisions

The provisions of the ordinance are based on the following considerations:

1. Diseased poultry may be a source or reservoir of diseases transmissible to man, including salmonellosis, erysipelas (causing erysipeloid in man), Newcastle disease, psittacosis, and various dermatoses.

2. Body discharges and dust from live poultry may be a source of pathogenic organisms, including those of the colon and paracolon types.

3. Insects may contaminate foods with etiological agents which may cause diseases such as typhoid fever, bacillary dysentery, and paratyphoid fever.

4. Rodents may contaminate water and food with hair, feces, and urine. Particularly noteworthy is the fact that *Leptospira icterohaemorrhagiae* excreted in the urine of wild rats has been reported as a principal cause of leptospiral infections in man. Rodents may be carriers of salmonellosis, lymphocytic choriomeningitis, tapeworms, and protozoans.

5. Poultry-processing wastes contain those organisms found in the body discharges of poultry, such as the *Salmonella* and other colon and paracolon types.

6. Sewage, if not properly disposed of, may be a direct or indirect source of contamination of foods with pathogenic organisms causing such diseases as bacillary dysentery, typhoid fever, and paratyphoid fever.

7. Water and ice not known to be safe may contain those species of organisms which cause such diseases as bacillary dysentery, leptospirosis, typhoid fever, and paratyphoid fever.

8. Infected employees may transmit diseases directly to fellow employees. They may contaminate foods with the causative organisms of such diseases as bacillary dysentery, salmonellosis, typhoid fever, paratyphoid fever, tuberculosis, and staphylococcal and streptococcal infections.

9. Extraneous materials in foods may cause physical injury to the consumer or be a source of contamination; rodenticides, insecticides, and various chemicals may be poisonous to man if consumed.

10. Proper refrigeration is necessary to prevent growth of micro-organisms and production of toxins in poultry and poultry products.

11. Food products offered for sale should be plainly identified and labeled with no misrepresentation.

12. The standards of consumer expectancy for foods, have, in effect, been delineated by Congress in the definitions of adulteration and misbranding as contained in the Federal Food, Drug, and Cosmetic Act; whether at the Federal, State, or local level, food-control regulations should be designed to obtain compliance with these standards.

Potential Values

The full value of the Public Health Service poultry ordinance will not be determined until it has been adopted, or at least used as a guide, by several State or local agencies as a basis for their poultry regulatory programs.

Experience in State and local milk sanitation activities has shown that the value of regulatory programs affecting food is greatly improved by a uniformity, within many jurisdictions, of requirements and enforcement procedures. This is not an interstate problem only. Uniformity of regulations and acceptance of products between local jurisdictions within a State can often be just as important to those concerned as is the case with products shipped from one State to another. There is ample reason to believe that adequate, uniform poultry regulatory programs will be of benefit to the poultry industry, the consumers, and the enforcement agencies concerned.

Such uniform programs will assist the industry in maintaining the gains of recent years and in making further progress through wide distribution of an ever greater variety of products. They will help to assure acceptance of products by the regulatory officials and by the consumers of other jurisdictions, making possible the competition which is essential for an expanding industry.

Industry members will be relieved of the ex-

pense and uncertainty of attempting to conform to conflicting requirements within the various jurisdictions where they may wish to distribute their products and will profit from increased sales in the communities where all poultry and poultry products offered for sale are consistently of high sanitary quality.

Employees' increased pride in their duties and their place of employment will contribute to increased efficiency and better products, resulting in better public relations. There will be less employee turnover, and the expense of training inexperienced personnel will be reduced.

Consumers in affected jurisdictions will receive the inestimable benefit of improved health protection and the assurance that products purchased meet standards of consumer expectancy. They will buy and enjoy with confidence the poultry and poultry products offered for sale in their community. While traveling on business or vacation trips through other jurisdictions having comparable requirements and enforcement procedures, they will have similar confidence in the wholesomeness of poultry dishes served to them en route.

It is significant, also, that uniform regulations and acceptance of products from other jurisdictions contribute to the variety of nutritious and appetizing foods available at competitive prices. Such variety and prices are directly essential to the health and happiness of the average consumer.

Regulatory agencies will benefit from the active cooperation of the poultry industry. This cooperation will be forthcoming only when the regulations are uniform, reasonable, and consistently enforced.

Widespread uniformity of regulations will help resolve the difficult, and sometimes costly, problems which face the regulatory agency in deciding whether to permit the sale of food products from other jurisdictions.

These safeguards for the health and interest of employees and consumers will be recognized and will result in respect and support of the regulatory agencies.

technical publications

VD Fact Sheet

Public Health Service Publication No. 341. December 1955. 21 pages; 15 tables.

Basic statistics on various aspects of the venereal disease control problem have been compiled to provide a handy source of information for those persons interested in public health and venereal disease problems.

In tabular form are estimated annual costs of uncontrolled syphilis, reported mortality and insanity due to syphilis in continental United States, and cases of syphilis and gonorrhea reported to the Public Health Service. Analysis of syphilis morbidity by age, results of penicillin therapy in the treatment of congenital syphilis and secondary syphilis as well as results of health department case-finding activities are also included.

Explanatory text accompanies the tables. Information is current as of the date of publication and supersedes any previously published data.

The Child With Rheumatic Fever

Children's Bureau Folder No. 42. 1955. 13 pages. 10 cents.

The most recent folder in the Children's Bureau series, addressed to

parents and covering conditions that cripple, or may cripple children, emphasizes the preventive value of early diagnosis and treatment of a strep throat—a condition which usually precedes an attack of rheumatic fever. It describes the role played by such medicines as penicillin and the sulfa drugs in combating the infection.

Only a doctor can determine when a child has a strep throat, the folder points out. Listed are signs the parents should call to the doctor's attention.

The folder covers the care of the child who already has rheumatic fever and makes suggestions that will help in keeping him content during the important, and often lengthy, convalescent period.

Reading on Cancer. An Annotated Bibliography

Public Health Service Publication No. 457. 1955. 16 pages. 15 cents.

Books, pamphlets, reports, and articles in popular periodicals and professional journals are included in this 1955 bibliography on cancer, prepared by members of the Cancer Reports Section of the National Cancer Institute. Major emphasis is given to information from nontechnical sources, and, for the most part,

the references are not more than 5 years old. Only material in the English language is included.

A section entitled "Related Reading" lists references on such subjects as atomic energy, medical research, popular science, and science-health career opportunities. There are also references in the field of geriatrics, preventive and psychosomatic medicine, and medical history and biography. After each entry, the letter "E," "M," or "D" appears in parentheses showing whether the material is "easy reading," "moderately difficult," or "difficult." All the entries are annotated, and a topical index is included.

Booklists provide bibliographies of professional material for detailed study of specific aspects of cancer, and sources of cancer information are given.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

Organized efforts to increase group enrollment in health insurance in four communities in a western North Carolina county produced impressive results, especially with farmers and low-income rural families.

Extending Voluntary Health Insurance Through Community Organization

By DONALD G. HAY, Ph.D., and SELZ C. MAYO, Ph.D.

EXISTING GROUPS can be of major help in extending programs for prepayment of health care costs, and this paper reports how community organization functioned to promote health insurance enrollment in one rural area.

In 1951, group enrollment in health insurance was a specific activity of the Haywood County (N. C.) Community Development Program. Most organized communities in Haywood County are of the open-country type, and the area here reported includes four such localities (1), each known locally as a community. Sociologically, these localities are more "neighborhood" than "community" in character since none has a population center with a complete set of trade and other services. The communities have very few special interest organizations

other than churches and a home demonstration club sponsored by the agricultural extension service.

Community Organization

In 1949, the agricultural extension service, in cooperation with other professional workers, began a program in Haywood County through which the local residents of each open-country community would undertake a community development program. Because there were few special interest organizations in these communities, coordination of activities was not a problem.

The organizational structure created to carry out the development program is known locally as the community club. The community club performs the major functions of study and planning and directs specific actions within the community. In the literature dealing with community organization, this type of organizational structure is classified as a form of the direct type of community organization.

Each of the four locality groups in the study contained a community club. In 1954, these clubs carried out their development programs through the following officers and committees:

1. Chairman, vice chairman, secretary, treasurer, and reporter. These officers were elected at regular, communitywide meetings.

Dr. Hay is social science analyst, Agricultural Marketing Service, United States Department of Agriculture, with headquarters in the department of rural sociology, North Carolina State College of Agriculture and Engineering, Raleigh, N. C., and in the division of health affairs, University of North Carolina, Chapel Hill, N. C. Dr. Mayo is professor of rural sociology, department of rural sociology, North Carolina State College of Agriculture and Engineering.

2. Six standing committees: survey, planning, program, recreation, refreshment, and scrapbook.

3. Special committees appointed to develop particular farm production enterprises for the community: tobacco, corn, hay, pasture, beef, dairy, and poultry.

4. Other committees designed to promote development of health, foods and nutrition, roads, and youth activities.

A study (2) was made of the organizational structure, operational procedures, and programs of one of these communities. Regular communitywide meetings are held each month in the educational wing of a local church. One of the most pressing needs, consequently one of the goals for 1954, was construction of a new center to be used for meetings and other community activities and to aid in the development of educational work in the community. A special committee was charged with this responsibility.

Each community meeting opens with devotions. A business session follows, during which plans are made, new programs are adopted, and committee reports are presented. Next there is an educational program, which may be centered on agricultural practices, international relations, such as a film on rural life in India, or explanations of a voluntary health insurance plan. The meeting closes with a recreation and refreshment period, which may include community singing and a supper or light refreshments.

One of the first steps in each community during the period of creating the community club was to identify the community boundaries. When this decision had been reached by the original interested group, community identification signs were erected on each road or highway running through the community. These signs circumscribe the community and, in a highly organized county, virtually every family is a member of the community "in-group," as determined by these boundaries. It is particularly necessary to emphasize the importance of this operational procedure since it is through this means that the identity of the "group" is determined for the voluntary health insurance program.

There are no dues and no membership rolls

for the community meetings; the number of families in the in-group is determined by community boundaries, not by the number of families whose members attend the meetings. To aid in understanding the actual operation of the voluntary health insurance program of the communities, one other aspect of the organizational structure in Haywood County must be noted in some detail, the county organization of the community development program.

The county organization was designed to coordinate and promote the activities of the community clubs throughout the county. In 1954, this work was carried out through the following officers, directors, and commissions operating under the name of the Haywood County Community Development Program:

County Officers. Chairman, vice chairman, reporter, secretary, and treasurer. County officers were elected from among community officers and members.

Board of Directors. Chairman, vice chairman, secretary, treasurer, and eight regular members. Both men and women were included. This group was responsible for developing policy and administering the community development program on the county level.

County Planning Commissions. County commissions were established in accordance with the major needs of the county and in accordance with the major activities of the community clubs. Countywide commissions were established or were to be created in connection with specific agricultural enterprises, recreation, and health.

This is the organizational structure and process within which the promotion of voluntary health insurance on a group basis is and has been pursued in Haywood County.

Group Health Insurance

The health insurance purpose of the Haywood County Community Development Program was stated in the 1951 Annual Report of the County Agricultural Extension Agent as follows: "The officers and directors of the community development program are very much interested in securing for the rural people of Haywood County the same benefits received by industrial and common-employer groups in

the county from group hospital and surgical insurance."

In addition to being an "organized community," each of the four localities had churches and one or more other organizations, such as home demonstration clubs. However, each organized community, in addition to being an integral unit of the countywide community development program, enjoyed a wide reach of participants through its embracive program of activities and, therefore, was in a key position to serve as a group base for enrollment in voluntary health insurance.

The possibility of developing a voluntary health insurance program was first discussed at a regular monthly meeting of each organized community. A local physician and a member of the countywide board of directors of the community development program presented general information on such insurance. The members, after some discussion, voted in favor of having the county board of directors proceed to seek a definite group health insurance plan.

During a period of 6 to 8 months, a specific plan was worked out with an insurance carrier and the necessary arrangements were made through the State Insurance Commissioner for the community development program to serve as a basis for enrollment in a group health insurance plan. The specific insurance program was presented at another regular monthly meeting of each organized community. Those participating actively at this second round of local meetings were local physicians, the local hospital administrator, a member of the county board of directors, and a representative of the insurance carrier. Community members voted to support the insurance program, and campaigns for enrollment in each community followed.

The fact that each community achieved the necessary 75-percent enrollment of all families, counting those already enrolled in a work-group employment plan, to qualify for the group enrollment arrangements reflects the strong local support given to the program.

In each community, a local person serves as chairman for the health insurance activity, collects premiums on a quarterly basis, and furnishes information on the insurance plan. He also is expected to stimulate new memberships

in the group enrollment plan, which is opened semiannually for new members. This local collector is paid a small fee by the members.

Group enrollment in voluntary health insurance through the Haywood County Community Development Program began in June 1951. Insurance was carried with a commercial insurance company for the first year. In June 1952, a nonprofit agency took on the health insurance program, and in January 1954 another nonprofit agency became the carrier. The community development program has been able to "weather" these two changes of health insurance carriers within a relatively short period of time, with all the attendant variability in some of the health insurance coverages and premiums.

Voluntary Health Insurance Enrollment

The strength of the enrollment effort in the four communities is reflected in the relatively high proportion of residents enrolled in the voluntary health insurance plan in June 1953, the time of the study. Two-thirds of the 299 households reported had some health insurance for one or more persons in the household; about three-fifths of the 1,222 individuals in these households had such insurance.

The following analyses are based on data for male heads of the households only. It is probable that the impact of community organization on health insurance enrollment for male heads of households represents the situation generally for all individuals in the localities studied.

The prominent role of group affiliation as the basis for subscribing to voluntary health insurance was impressive. There were 270 male heads of households, and 154 (57 percent) had health insurance. More than 9 of every 10 were enrolled on a group basis. More than 3 of every 5 male heads of households who had health insurance were enrolled on a group basis in industrial plants and in other group employment situations.

The direct contribution of the Haywood County Community Development Program to health insurance can be measured by the data showing that about two-fifths of all enrolled male heads of households were enrolled on the group basis sponsored by that program.

Only about 1 in every 7 enrollees had subscribed as individuals. Proportions are cumulative to more than 100 percent because of a few cases of enrollment in two or more types of health insurance.

The effect of contributions of the community development program to voluntary health insurance enrollment was further demonstrated by the program's particular ability to enroll two groups usually less available to health insurance—farmers and low-income households. Of all farm operators enrolled, 4 of every 5 in 1953 had enrolled in the group plan sponsored by the Haywood County Community Development Program. Of the enrolled male heads of households who had annual net cash incomes of less than \$1,500, 2 of every 3 had enrolled with the community group program. Although health insurance enrollment among farmers and other workers in nongroup employment, as well as male heads of households with low incomes, was still relatively low in the four rural communities in the study, the community development program's particular success in enrolling many of them encourages further efforts.

Conclusions

What do these data mean? What are the implications of this study? First, the results are sufficiently fruitful to indicate an area for further research. Several similar studies are necessary, however, before the results can be considered conclusive. The data in this single study appear to be sufficiently pointed to warrant consideration of possible action along three lines.

1. Voluntary health insurance carriers may need to reexamine their concept of "group." Groups of many kinds that do not charge dues or maintain membership rolls are found in communities. Such locality groups as neighborhoods and communities, when sufficiently organized, may be the means of reaching families living in open-country communities that are dependent upon agriculture for a livelihood, as well as other self-employed workers. Such a change in the concept of "group" may necessitate major alterations in many State laws and

administrative interpretations that relate to voluntary health insurance. In selecting personnel for selling and maintaining insurance in rural communities, carriers may need to consider this change in concept.

2. The implication of these data appears to be clear-cut for community leaders interested in health matters. Efforts in the direction of complete community organization, as contrasted with another special-interest group in health, appear to be fruitful for exploration. This seems to be a way of arriving at a "group" so as to take advantage of a group basis for voluntary health insurance. Also, this procedure opens channels of communication and uses social control techniques which are not possible under many other conditions. Through this procedure, some open-country families can be reached more adequately than through more specialized groups.

3. In training public health personnel, as well as personnel of other agencies functioning in rural areas, institutions may need to alter their training programs to include, or expand, community organization principles, procedures, and techniques. Professional personnel must give more attention to leadership training of lay persons for the assumption of communitywide responsibility. These agencies are in rural areas for the purpose of aiding rural people to raise their levels and standard of living. Health is generally recognized as one of the important aspects of levels and standards of living and many persons are of the opinion that voluntary health insurance is an important element in improving the health status of rural residents. It would appear that all agencies working in rural areas must in the future give more attention to community organization.

Continued High Incidence of Diphtheria in a Well-Immunized Community

By W. J. MURPHY, M.D., M.P.H., V. HAMILTON MALEY, M.D.,
and LILLIAN DICK, B.S., R.N.

THE incidence of diphtheria in the United States has steadily declined during the past few decades. Morbidity and mortality have decreased in each of the various geographic areas, but not to a similar extent (1,2). The most abrupt drop has occurred in the Northeast, which prior to 1920 reported the highest rates in the country. In contrast, the most leisurely decline was observed in the South. At present, the rates reported from several of the southeastern States, including Georgia, are among the highest in the Nation.

Although evidence indicates that the abrupt drop in diphtheria morbidity during the past 25 years is related to the widespread use of active immunization, it is generally agreed that other factors have contributed to the decline. It is probable, too, that current variations in incidence in different areas may be due, in part, to factors unrelated to artificial immunization.

In an area of north Georgia comprising 10 counties with a combined population in 1950

of 156,175, the average annual morbidity rate for 1949-53 was 26.2 per 100,000 population as compared with a rate of 7.6 for the State. At the center of that area is Hall County, which reported an average annual rate of 47.8 during the same period. This report deals primarily with the diphtheria experience of Hall County.

Hall County, Ga., is located in the Piedmont Plateau of the foothills of the Appalachian Mountains and had a population of 40,113 in 1950, approximately 10 percent of which was Negro. Gainesville, the principal city, had a population of 11,936. On the whole, the county is prosperous and ranks in median family income among the upper 15 percent of Georgia's 159 counties.

Medical, public health, and hospital facilities are considered adequate. Since 1921, Hall County has had an organized health department with full-time professional personnel. Gainesville has a modern hospital with 114 beds. In 1953, there were 27 practicing physicians in the county.

Dr. Murphy is director of the division of epidemiology, Georgia Department of Public Health, Atlanta, Ga. Dr. Maley is commissioner of health for Hall County, Ga. Miss Dick, on assignment to the Georgia Department of Health at the time of this study, is now public health nursing supervisor and coordinator, Public Health Service Outpatient Clinic, Washington, D. C.

Diphtheria Incidence

From 1935 through 1953 no appreciable decline was observed in the diphtheria incidence in Hall County. This is shown in table 1 which compares the county's average annual morbidity and mortality rates with those for the State.

In view of the small Negro population in

Only about 1 in every 7 enrollees had subscribed as individuals. Proportions are cumulative to more than 100 percent because of a few cases of enrollment in two or more types of health insurance.

The effect of contributions of the community development program to voluntary health insurance enrollment was further demonstrated by the program's particular ability to enroll two groups usually less available to health insurance—farmers and low-income households. Of all farm operators enrolled, 4 of every 5 in 1953 had enrolled in the group plan sponsored by the Haywood County Community Development Program. Of the enrolled male heads of households who had annual net cash incomes of less than \$1,500, 2 of every 3 had enrolled with the community group program. Although health insurance enrollment among farmers and other workers in nongroup employment, as well as male heads of households with low incomes, was still relatively low in the four rural communities in the study, the community development program's particular success in enrolling many of them encourages further efforts.

Conclusions

What do these data mean? What are the implications of this study? First, the results are sufficiently fruitful to indicate an area for further research. Several similar studies are necessary, however, before the results can be considered conclusive. The data in this single study appear to be sufficiently pointed to warrant consideration of possible action along three lines.

of the immediate family but not from the patient. In 12 of these instances, cultures were gravis in character and 1 was indeterminate.

Immunization Status

The immunization status of 96 diphtheria patients (1949-53) was obtained from their clinical records. Patients recorded as having received one or more doses of an immunizing agent were separated into two groups: (a) those who had received at least 3 doses of an antigen, the last one within 3 years of the date of illness; and (b) all others who had received at least 1 dose. The first were considered to represent immunization failures while in the second group protection was classed as inadequate or lapsed.

Information as to prior immunization was available for all but 14 of the 96 cases. The findings are summarized below.

Immunization	Number cases
None.....	48
Inadequate or lapsed.....	27
Immunization failure.....	7
Unknown.....	14

Of the 27 patients for whom immunization was recorded as being inadequate or lapsed, 5 had received one dose and 3 had received 2 doses of alum-precipitated toxoid within 3 years of the date of illness. For the remaining 19, there was an interval of more than 3 years between the date of the last inoculation and the onset of illness.

The 34 patients in the inoculated group in-

cluded 12 preschool and 22 children of school age, 7 boys and 27 girls. This apparent sex difference may be of some significance since a similar preponderance of cases among girls in inoculated groups has been reported by other workers (4).

In the unimmunized group there were 36 preschool and 10 school-age children and 2 adults above age 30. Of these 48 patients, 25 were males and 23 females.

Four of the 96 diphtheria patients died. None of the four had received an immunizing agent.

Active Immunization

In April 1953, a study was made of the extent to which active immunization was being employed in Hall County. For that purpose, a 10-percent sample of recorded live births during 1948-51 was obtained by selecting every 10th name from an alphabetical list prepared by the Georgia Division of Vital Statistics. The names appearing in the sample were checked against the records of the Hall County Health Department. Those not appearing in the files were checked against the records of three pediatricians. The remaining names that failed to appear in the physicians' records were arranged alphabetically, and a 20-percent sample was obtained by selecting every fifth name. The homes of the selected children were visited. If there was a history of prior immunization, the name of the physician administering the inoculations was obtained and his office was visited. A child was included in the

Table 1. Average annual morbidity and mortality rates per 100,000 population for Hall County and for Georgia, 1935-53

Years	Georgia		Hall County	
	Mor- bidity	Mor- tality	Mor- bidity	Mor- tality
1935-39-----	35.3	3.9	31.0	3.0
1940-44-----	18.4	1.7	35.6	1.7
1945-49-----	14.1	1.2	66.7	2.6
1950-53-----	6.4	.4	28.8	2.4

Hall County, the white and Negro rates are not considered separately. Until recently, the reported incidence of diphtheria in the white population was considerably above that for the Negroes. The rate for the white population has declined more rapidly, however, and since 1952 it has been slightly below the rate for Negroes.

The age distribution of diphtheria in Hall County does not differ appreciably from that of the State. At present in Georgia approximately 85 percent of all cases are reported in children below the age of 15 years, the highest rate being observed in the group 5 to 9 years old.

During the 5-year period 1949-53, diphtheria occurred in all sections of the county with relative frequency. Of the 96 cases reported for the period, 28 occurred in Gainesville and 68 in the remainder of the county. The average annual rates per 100,000 population for the 2 areas were 46.9 and 48.2, respectively. No undue concentration of cases was apparent in any particular occupational group. In keeping with the seasonal rise in incidence observed throughout the State, 50 percent of the cases were reported in October and November.

Diagnostic Criteria

To evaluate the criteria of diagnosis, we reviewed the records of the 96 cases of diphtheria reported during 1949-53. Primary consideration was given to: (a) the occurrence of a febrile illness of several days' duration; (b) evidence of a localized infection as indicated by a membrane in the throat, laryngeal involvement, or both; and (c) laboratory studies. In approximately four-fifths of the cases the local

and constitutional symptoms and the laboratory findings were consistent with a diagnosis of diphtheria. Some patients were described as having a febrile illness, sore throat, and a positive culture, but they lacked a typical membrane. In the remaining cases, the diagnosis was based on clinical grounds, characteristically on the appearance of the membrane. Apparently, the diagnostic criteria in Hall County were comparable to those in other areas of the State.

Cultures

Since October 1948 all virulent diphtheria cultures received by the central laboratory of the Georgia Department of Public Health have been forwarded for typing to the Laboratory Branch of the Communicable Disease Center, Public Health Service. And since July 1950 virulent cultures received by the branch laboratories have also been forwarded for typing.

A total of 927 virulent cultures were submitted for typing from October 1948 through June 1954. This figure represents the number of persons from whom cultures were received, and it includes only actual cases and intimate contacts.

The different types of *Corynebacterium diphtheriae* found in the various areas of the State are shown in table 2. The classification method is the one used by Frobisher (3). Gravis strains predominated in north Georgia, particularly in Hall and adjacent counties, but comprised only a small proportion of the cultures received from central and south Georgia.

The area designated as north Georgia represents approximately the northern two-fifths of the State. It includes 59 counties, 9 of which are contiguous with Hall County.

Of the cultures received from Hall County, approximately one-third were obtained from clinical cases and the remainder from household contacts. In numerous instances, unfortunately, cultures from hospitalized patients were not forwarded for typing to the Georgia Department of Public Health. Of the 96 cases reported during 1949-53, cultures were received from 55, and, of these, 52 were gravis and 3 were mitis. In 13 additional instances, cultures were received from one or more members

children in the South (5, 6), the proportion of Schick-negatives was also found to be high, even among those who had never received an immunizing agent. Similarly, in Schick surveys of young men entering the armed services (7, 8), the frequency of positives among men from the South has been lower than among those from most other areas of the country. In view of the findings in previous surveys, the results in Hall County are not surprising when considered in connection with the high diphtheria morbidity and the extent of artificial immunization.

Discussion

The continued high incidence of diphtheria in Hall County is of interest in view of the general decline experienced throughout the Nation and in most areas of Georgia. Although it is conceivable that a variety of factors may have contributed to the Hall County experience, this study has been concerned primarily with the extent of active immunization, the prevailing strain of *Corynebacterium diphtheriae*, and the frequency with which clinical infections occurred among the immunized.

Hall County has had an organized health department for more than three decades and during most of that time immunization against diphtheria has been stressed by health officials and physicians alike. That the program has been reasonably successful in reaching a large proportion of the preschool population is indicated by the results obtained in checking a sample of live births against available immunization records. Although the estimates based on that sample cannot be readily compared with those reported from other areas in the past, immunization apparently has been used more extensively in Hall County than in numerous other localities (9-11), which have experienced a far lower incidence of diphtheria for a number of years. Obviously, the Hall County experience cannot be attributed solely to a lack of interest in active immunization. On the contrary, the incidence of diphtheria has continued at a high level despite a well-organized immunization program.

On the other hand, the evidence indicates that the use of a diphtheria antigen afforded

an appreciable degree of protection when recommended schedules were followed. In view of the proportion of children who had received an immunizing agent, 60 percent by the age 1 year and almost 100 percent by the age of 6 years, it is apparent that clinical infections were observed much less frequently among those who had received one or more inoculations. Moreover, of the infections observed in the inoculated group, the great majority occurred following inadequate dosage or after protection had been permitted to lapse.

It is possible that the high diphtheria incidence in Hall County may be associated with an unusually aggressive strain of *C. diphtheriae*. Since October 1948, when routine typing was begun, more than 90 percent of the cultures from that county and almost 70 percent of the cultures from neighboring counties have been gravis strains. The findings are in sharp contrast to the diphtheria flora usually encountered in other areas of the United States (12-14). Moreover, the serologic studies reported by Hermann and Parsons (15) indicate that the gravis strains isolated in north Georgia are closely related antigenically.

However, the clinical manifestations of the disease have not been unusual and case fatality rates have not been excessive, even among the unimmunized.

The association of a gravis strain with the continued high incidence of diphtheria in Hall County is not necessarily peculiar to that type of *C. diphtheriae*. Presumably, other types might be involved elsewhere in similar situations.

Summary

From 1935 through 1953, the incidence of diphtheria in Hall County failed to decline in spite of a well-organized immunization program.

A study based on a sample of live births indicates that at least 60 percent of the infants born in the county receive an immunizing agent by the age of 1 year. By the age of 6 years, the figure approaches 100 percent.

A review of the diphtheria cases reported during the period 1949-53 indicates that active immunization afforded an appreciable degree

inoculated group only if an immunization record was on file. Those who had moved from the county were considered unimmunized. Infants who had died prior to the study were not excluded from the tabulations.

The 10-percent sample of live births for the period, 1948-51, included 395 names. The records of the Hall County Health Department and those of three pediatricians showed that 239 had received one or more doses of a diphtheria antigen. In 192 instances, the inoculations had been given during the first year of life. Since a considerable period of time is required in administering multiple doses of an antigen, the date of the first inoculation was used.

For the most part, a combined diphtheria-tetanus-pertussis antigen had been administered, although during 1948 and 1949, the primary series sometimes consisted of 2 doses of alum-precipitated toxoid. Of the 239 infants for whom immunization records were on file, 184 had received at least 3 doses of a combined antigen; 37 had received 2 doses of an antigen, chiefly alum-precipitated toxoid, and 18 had received only 1 dose.

There remained 156 names which did not appear among the immunization records. As stated previously, a 20-percent sample was obtained, and the 31 children in the sample were visited. A history of prior immunization was obtained for 12 children and verified by a visit to the physician's office. Of this group, 9 had been inoculated during the first year of life. For 12 children, there was no history of prior immunization and 7 families had moved from the county.

The proportion of Hall County children born during 1948-51 who had received an immunizing agent during the first year of life was estimated as:

$$\frac{192 + (5 \times 9)}{395} = 60 \text{ percent.}$$

The estimates of 68.3 percent for the second and 74.4 percent for the third year of life were similarly prepared.

The inoculated group included only children with immunization records, and since infants who died were not excluded and those who had moved from the county were considered un-

immunized, the actual immunization rate probably exceeded the estimated figures.

By the age of 6 years, the proportion of inoculated children in Hall County approached 100 percent. Prior immunization against diphtheria is a requirement for entrance to school, and although the regulation is not rigidly enforced, comparatively few children fail to comply with it. It is also routine practice for representatives of the health department to visit the schools in the fall and to administer recall doses to those in the lower grades who have not received one within 3 years.

Schick Tests

In December 1953, the children in 1 Negro and 2 white schools were Schick tested. The test group included 1,838 children ranging in age from 6 to 18 years. Both urban and rural areas were represented. Tests were made by injecting intradermally into the forearm 0.1 cc. of an appropriate dilution of a standard diphtheria toxin. Control tests were not employed. Readings were made on the sixth day and doubtful reactions were read as positive. Since the findings in each school group did not differ appreciably, they were considered together (table 3).

Even assuming some margin of error in connection with the technique employed, it is apparent that comparatively few school children in Hall County are Schick positive. This obviously implies an unusual immunization rate, either natural or artificial, or both.

In a number of previous surveys of school

Table 3. Number and percent of positive Schick tests by age, Hall County, Ga., December 1953

Age (years)	Number tests	Number positive	Percent positive
All ages	1,838	106	5.7

Questions put to homemakers in Rochester and Syracuse, N. Y., evoke a striking relation between knowing and doing.

Nutritional Knowledge and Practices

By CHARLOTTE M. YOUNG, Ph.D., KATHLEEN BERRESFORD, M.S.,
and BETTY GREER WALDNER, M.N.S.

WHY are some people less well fed than they might be, even when their income is sufficient? A study in New York State demonstrated that in a number of families where there were dietary inadequacies lack of income was not the primary cause (1). May one explanation be that homemakers do not know what to feed their families to provide a nutritionally adequate diet? Studies in Richmond, Va., in 1947 indicated that adequacy of family feeding might be related to the level of homemakers' knowledge about food and nutrition (2).

Public health workers, teachers, extension workers, and school lunch managers are interested in determining what knowledge about food and nutrition the homemaker applies to feeding her family. On what nutrition subjects have we succeeded in educating the homemaker? Where do we need to do better? What problems do homemakers have in planning, buying, or preparing food for their families? Do they seek help with these problems? What kinds of help? Where has the homemaker obtained her present information on food and nutrition?

In an attempt to answer some of these questions, we studied the food and nutrition knowl-

edge and practices of cross-sectional representative samples of homemakers in two upstate New York cities, Rochester and Syracuse, in the early fall of 1953.

Survey Techniques

Data were collected by trained interviewers directly from homemakers, that is, persons responsible for planning family meals. The interview used pretested open-end questions. The interviewer recorded responses as nearly as possible in the homemaker's words. Ninety-six questions were asked. An average interview lasted 1 hour.

Sampling was directed by P. J. McCarthy, director of the Cornell University Statistics Center, Ithaca, N. Y. Within the city limits of Rochester, population 332,488, and Syracuse, population 220,583 (1950), sample blocks were drawn with probability proportionate to size, based on the census of housing block statistics for 1950. All private dwelling units in the sample blocks were listed, and those to be interviewed were selected by a field supervisor in a central office in accordance with a scheduled sample interval starting with a random number. Validation of the samples by comparison with statistics from the 1950 census is reported in detail elsewhere (3). The educational attainment level of the homemakers in the Syracuse sample was somewhat higher than that of Syracuse women reported in the 1950 census. No single-person dwellings were used.

Completed interviews in Rochester numbered

Dr. Young is professor of medical nutrition, Mrs. Berresford was an assistant professor of public health nutrition, and Mrs. Waldner was formerly an instructor in the School of Nutrition, Cornell University.

of protection. Of the cases observed among previously inoculated children, the great majority occurred following inadequate dosage or after protection had been permitted to lapse.

Since October 1948, more than 90 percent of the cultures received from Hall County have been gravis strains. In central and south Georgia gravis strains were encountered infrequently.

The clinical manifestations of the disease in Hall County have not been unusual.

Warns Against Hoxsey Treatment

An official public warning against use of the Hoxsey treatment for internal cancer was issued April 4, 1956, by the Food and Drug Administration.

The warning was based on the finding by the United States Court of Appeals for the Fifth Circuit that the treatment was worthless. Analysis of the contents of the liquids and pills issued by the Hoxsey clinics at Dallas, Tex., and Portage, Pa., showed no value in the cure of cancer and that they contained potassium iodide, a compound which has been indicated as one that may accelerate growth of some cancers. In addition, the Food and Drug Administration, despite a thorough study, stated it had not found a single-verified cure of internal cancer effected by the Hoxsey treatment.

An injunction obtained October 26, 1953, prohibits the shipment of Hoxsey "medicines" in interstate commerce if the labeling represents, suggests, or implies that they are effective in the treatment of any type of internal cancer.

could not do so for any group, "no knowledge"; and those in between, "some knowledge."

The conventional foods, such as meat or meat substitutes and potatoes and other vegetables and fruits, were mentioned for inclusion in meals by almost all of the homemakers. Only a few in the study mentioned items more likely based on nutritional knowledge than custom.

None of the homemakers mentioned all 7 of the basic food groups; only 3 percent named 6 of them; an additional 12 to 14 percent, 5. The great majority mentioned only 3 or 4 groups.

Only one-third to one-half of all the homemakers had enough knowledge to give correct reasons for inclusion of any of the food groups. Again meat or meat substitutes, potatoes and other vegetables and fruits, and the milk group were best known. Only 3 to 6 percent of the homemakers knew a reason for including vitamin C-rich fruits; 7 to 10 percent, carotene-rich fruits and vegetables; 4 percent, butter or fortified margarine; 16 to 19 percent, bread, flour, or cereals.

Assessment of nutritional knowledge was based on the number of food groups for which each homemaker could give a correct reason for inclusion in her family's meals. Nineteen percent of the Rochester and 30 percent of the Syracuse homemakers gave evidence of an adequate knowledge as defined in this study; 32 and 36 percent, some knowledge; 34 and 49 percent, no knowledge.

Approximately one-fourth of the homemakers in both cities defined a balanced diet in such a way as to show the expression was meaningful to them. Two-thirds to three-fourths of the homemakers said they had never heard of the basic seven. Only 10 to 20 percent who had heard of the term could name at least one of these food groups.

The percentage of homemakers in each city who could name possible nutritional substitutes for each of three basic foods is shown in table 2. Again, the meat group was best known.

The younger and better educated homemakers definitely displayed more knowledge of nutrition than the older and less well educated. Since age and educational level proved to be closely associated, it was felt that educational

level was the determining factor. There was no consistent relationship between family income level and the homemaker's knowledge of nutrition. What income influence appeared to be present was found to be due largely to educational differences. This finding occurred when the income and educational influences were segregated by two-way tabulation for any given measure of nutritional knowledge. Details of these relationships and supporting data are reported elsewhere (4).

In Rochester there were 35 percent and in Syracuse 40 percent of the homemakers who reported they had "studied about what to eat." Most of them had studied the subject in public school. Only a few reported study under other circumstances such as courses offered by the Red Cross, home bureau, and cooking schools. Regardless of which measure of nutritional knowledge was used, a higher percentage of homemakers who had studied about what to eat had some knowledge of nutrition which was lacking in those who had not studied.

Performance

In relating the performance of the homemaker in feeding her family to her knowledge of nutrition, we considered: (a) recall by the homemaker of foods served her family in the previous 24 hours and whether or not the meals had been typical; (b) recall of beverages (separately for children and adults) served at each meal; and (c) quantitative information obtained by the homemaker's recall of the amounts of certain key foods used during the previous week.

Family income and age and education of the homemaker were related to performance, and nutritional knowledge was related to performance on a group basis. The practices of home-

331 and in Syracuse, 315, representing in each city 63 percent of the sample drawn. The disposition of the rest of the sample drawn included 12-percent refusals in Syracuse and 14 percent in Rochester. The most frequent reasons given for refusals were "not interested," or "too busy," but they also included serious illnesses or recent deaths in the families, inability to speak English, apparent mental incompetency, and refusal to answer the door. The remaining 25 and 23 percent of the sample drawn were accounted for almost equally by single person dwellings and by families not at home on at least three interview attempts at different times of the day and evening.

Responses to various parts of the questionnaire were tabulated and related to the following factors: age group of the homemaker, her level of formal educational attainment, whether or not she had ever "studied about what to eat," and family income level. The age groups used included the following: young (under 40 years of age), middle-aged (40 to 60), and older (over 60). Homemakers were grouped in three levels of educational attainment—those who had not attended high school, those who had attended but not completed high school, and high school graduates. Divisions used for family income level were under \$3,500, \$3,500–\$4,999, and \$5,000 or over.

The homemaker's knowledge was assessed according to her response to a number of questions. Among others these included:

1. What do you feel should be included in the meals for your family each day? Why do you feel (name of food) should be included? Why does your family need that?

2. Maybe you have heard or read about a so-called balanced diet. What does a balanced diet mean to you?

3. Do you know what is meant by the "basic seven"? What are the groups in the "basic seven"?

4. What other foods could be used in place of milk? When you do not wish to serve meat, fish, or poultry, what foods do you think you can serve in their place and get some of the same food value? When you do not have oranges or grapefruit is there anything you can serve that would give you about the same food values? What?

Nutritional Knowledge

Response to the question of what should be included in the family's meals each day is shown in table 1. If a homemaker named an important nutrient contribution or nutritional function served by the food group mentioned, the interviewer credited her with giving a correct reason. For example, in answer to questions about why meat and milk should be served each day, typical correct replies might include:

Meat—"because it has lots of iron" or "because it builds good red blood" or "protein" or "because it builds muscle."

Milk—"for strong bones and teeth" or "because it has lots of calcium."

In contrast, replies such as "good for you," "to grow," "because we like it," or "need it" were not interpreted as indicating specific nutritional knowledge. Those who could give a correct reason for three or more groups were said to have "adequate knowledge"; those who

Differences were evident in the groups where knowledge might be expected to be causative. Of homemakers who had an adequate knowledge of nutrition, those who used all seven of the basic food groups in their meals were a far greater proportion (48 percent) than of those with no knowledge (31 percent). Also, more homemakers with an adequate knowledge (76 percent) served nutritionally good breakfasts than did those with some or no knowledge (62 and 51 percent, respectively).

Knowledge of nutrition appeared to be re-

lated to performance as measured in more quantitative terms also (table 5). There was a smaller percentage of homemakers with an adequate knowledge of nutrition in the category of those using less than 50 percent of their families' suggested needs for milk and citrus fruit.
